Lecture

ON

HEPATOPTOSIS, GLÉNARD'S DISEASE, AND MOVEABLE KIDNEY.

Delivered at the Medical Graduates' College and Polyclinic on Feb. 12th, 1906,

BY W. WATSON CHEYNE, C.B., LL.D., F.R.S., F.R.C.S. ENG., &c.,

SENIOR SURGEON TO KING'S COLLEGE HOSPITAL; PROFESSOR OF CLINICAL SURGERY, KING'S COLLEGE, ETC

GENTLEMEN,—Mobility of various abdominal organs is a [illegible] which is fully recognised as occurring in a certain number of instances, but I doubt if its significance, gravity, and frequency are adequately appreciated. The symptoms [illegible] may arise in connexion with these conditions are so [illegible] and so vague and are associated with such disturb-[illegible] of the nervous system that the sufferers are often put down as neurotics and their ailments as fanciful exaggerations. Nevertheless, I believe that in many of these supposed hysterical cases the troubles are very real and are due to [illegible] descent of one or other or all of the abdominal viscera. This mobility may affect one or several of the [illegible] organs. Those chiefly concerned are the kidney, the liver, the stomach and intestines, and the spleen. I shall [illegible] shortly to the first three.

MOVEABLE KIDNEY.

This is the most common and most generally recognised condition and it may occur alone or in association with general mobility of the abdominal organs. Most often the latter is the case. The right kidney is the one chiefly ected. The condition varies from slight mobility to a freely moveable or "floating" kidney. It may occur [illegible]ly; that is, the patient may have been making some violent exertion or been subjected to some severe strain and then have pain in the side, usually the right, and on examination descent of the kidney can be detected. Here there is probably a true dislocation of the organ. Or, again, [illegible] patient consults a surgeon on account of some or other [illegible] the symptoms mentioned below and on examination a moveable kidney is found. Or, again, a moveable kidney is found during the course of an abdominal examination without any symptoms pointing in that direction having been present. In the two latter cases the mobility of the kidney may have existed for a long time and the pedicle has no [illegible] gradually stretched as time went on. In some cases [illegible] may be induced and it is certainly aggravated by injudicious application of corsets; it may occur where a patient rapidly emaciates; or after distension of the abdomen [illegible] in pregnancy, where the abdominal walls become lax for [illegible] time; and it is commonly present in cases of hepatoptosis and enteroptosis.

In connexion with mobility of the kidney we may have great variety of symptoms. A slight degree of mobility or very marked degree such as that known as floating kidney [illegible] give rise to no symptoms. The intermediate cases [illegible] the kidney can descend into the loin but not further [illegible] the important ones. To some extent this is because the [illegible] comes to lie in a position where it is subject to [illegible] from corsets, waist bands, &c., or is affected by [illegible] of the body. In such cases the patients complain [illegible] dragging pains in the back and side and general abdominal discomfort, and these troubles are still more [illegible] if the mobility of the kidney is associated with hepatoptosis or enteroptosis. These symptoms are probably due to the weight of the organ and consequent dragging [illegible] the pedicle. More serious symptoms may, however, [illegible]ually arise. For example, the kidney may from time to time press on the duodenum, causing temporary obstruction, with vomiting, pain, and a group of symptoms known [illegible] Dietl's crises, and if this is frequently repeated or long [illegible] it may lead to dilatation of the stomach and general dyspepsia. A variety of troubles may also arise in connexion with the kidney itself. It tends to become congested from time to time from obstruction to the vessels, while kinking of the ureter may also take place, leading to attacks of intermittent hydronephrosis. This latter condition, whether associated with kinks in the ureter or malposition of the ureter with reference to the pelvis, &c., chiefly occurs where the kidney is moveable.

Much dispute exists as to how far the symptoms of which these patients complain are really due to the mobility of the kidney or are essentially of a neurotic character. This question can hardly concern the severer cases (Dietl's crises, intermittent hydronephrosis, &c.) which are too definite to be neurotic, but has special reference to the cases where there are merely pain in the back and side and a general sense of discomfort. Some look on the local and general symptoms in these instances as essentially neurotic in character and the mobility of the organ as of comparatively little moment, while others regard the mobility as a serious condition and the various symptoms as being directly due to it. The point is a very important one, as the line of treatment adopted by different practitioners depends on the view they take.

The treatment of moveable kidney is either to ignore it or to attempt in various non-operative ways to keep it in its place and to relieve the symptoms or to fix it by operation. As to the first suggestion, that of ignoring it, so long as the condition is giving rise to no symptoms whatever and has only been found accidentally on examination I presume all are agreed that it is best to ignore it and in no way to draw the patient's attention to it. Where, on the other hand, very marked symptoms are present—e.g., Dietl's crises, intermittent hydronephrosis, hæmaturia, &c.—I have no hesitation in saying that operative treatment is essential, either fixation of the kidney alone or, where intermittent hydronephrosis occurs, fixation combined with such plastic operation on the ureter as may be considered necessary, or in bad cases even nephrectomy. It is the intermediate cases which are open to doubt. That there is often a large amount of neurosis in these cases is certainly true but I see no reason for doubting that the pains of which the patients complain are real; indeed, the wonder is that in some cases the kidney can move as it does without causing pain, and it is probable that it is the constant dragging pain and other symptoms which induce the neurotic condition.

Various methods of treatment are employed to remedy this looseness of the kidney and at the same time to improve the general neurasthenia without operation. For example, Weir-Mitchell treatment, followed by change of air and scene, has been much employed with varying success. Various pads and supports are fitted on to keep the kidney in place. Attempts are also made to increase the fat, &c., and so to get back the fatty pad. None of these methods are, however, really satisfactory and pads especially are very prone to become displaced in the movements of the abdominal muscles or so lifted up that the kidney slips down beneath them and is thus no longer supported and may, indeed, become injuriously pressed upon by the pad itself. Better than pads are probably Gallant's corsets, of which I shall speak later.

These attempts, however, frequently fail to relieve the patient completely and, where the symptoms continue to be constant and severe, the patient may still ask that something should be done. Then arises the question of nephrorrhaphy. Some physicians object to this operation *in toto*, their chief arguments being that the kidney may become loose again, that a good deal of pain may be set up by the operation, and that the whole symptoms may speedily recur, the recurrence being ascribed to, and accepted as a proof of, the essentially neurotic character of the trouble. These objections, however, are hardly sound. That the kidney has frequently become loose after nephrorrhaphy may have been true in the early days of the operation, but this is merely a matter of technique and it is really easy enough to fix the kidney satisfactorily. The essential points in the operation are, I think, firstly, the free removal of the fatty capsule, so that the kidney can come into close apposition with the fascia over the abdominal wall; and, secondly, free stripping up of the capsule of the kidney, so as to leave a raw place for adhesion. That pain may be left after the operation is also correct, but is, I believe, due in part to inclusion of dorsal nerves in the ligature and in part to the position in which the kidney is usually fixed. It is very difficult, indeed almost impossible, to fix the kidney as high up as it normally lies and usually a considerable part of it is left in the lumbar region below the ribs. In that situation it is subjected to the pressure of the corsets and bands for the clothing and much pain may thus be caused. It is, therefore, most important to fix the kidney as high up beneath the ribs as possible. For this purpose I believe that a free incision along the lower border of the ribs and parallel to them is best. It should be of considerable length; the peritoneum is pushed forwards and the kidney fixed high up. That the whole symptoms may recur when the patient gets up is also true, but I believe that the explanation is not that the symptoms associated with moveable kidney are essentially neurotic, but that in these unsuccessful cases the kidney condition is only part of a general enteroptosis and therefore the fixation of the kidney only does very little towards remedying the trouble; in fact, does not touch the essential part of it. Hence, while I advocate fixation of the kidney by operation in suitable cases where other means have failed and where the symptoms are sufficiently severe, I think that this question of enteroptosis ought to be looked into carefully before proceeding to operation and if there is evidence of hepatoptosis or enteroptosis these must be attended to before the kidney is dealt with. In any case of nephrorrhaphy the corsets recommended in speaking of enteroptosis should be worn afterwards.

HEPATOPTOSIS.

Abnormal mobility of the liver was at one time looked on as very rare but in reality it is not at all uncommon and is probably present to a greater or less degree in most cases of enteroptosis. It may also be responsible for many cases of vague abdominal discomfort, while when fully developed it produces most serious symptoms which will be presently referred to. In these cases the healthy liver becomes moveable and hangs down into the abdominal cavity as far as its attachments will allow and at the same time it undergoes marked rotation. It is freely moveable and may be replaced by manipulation. We must distinguish this condition from a simple "dislocation of the liver." A liver may be dislocated to some extent from its normal position by tight corsets, waistbands, spinal deformities, especially kyphosis, pleuritic effusions, &c.; but it merely lies lower than normal and does not undergo the rotation and change in position which occur in the other cases, and may not, therefore, give rise to serious trouble.

It is most important to bear in mind that the wandering liver does not merely descend from underneath the ribs, but, as it comes down, its descent is resisted towards the middle line, especially about the level of the junction of the right and left lobes, and thus the heavy right lobe continues to come down and to render this possible the whole organ has to rotate forwards and to the left. Thus the sinking of the right lobe leads to a corresponding rise in the left lobe and the whole organ becomes more vertical as well as being rotated; indeed, the liver may become so vertical that the left lobe in bad cases may be in the right hypochondrium, while the right lobe may reach to the pelvis. The hollow thus left under the right side of the diaphragm becomes filled up by the intestines. This displacement of the liver is a very important point to bear in mind, because it cannot be remedied by merely pushing the organ up; the rotation must be undone at the same time.

Another condition of the liver which is also not uncommon and which may or may not be associated with wandering liver is where the edge of the liver, generally of the right lobe, is flattened out and this thin layer of liver may extend downwards for a considerable distance and is generally marked off from the body of the liver by a deep furrow in which is much fibrous tissue. Various states of the liver may be found in which furrows caused by the pressure of the ribs or pillars of the diaphragm are present, but the above is the chief form which gives rise to symptoms and which therefore need be referred to. It is essentially due to wearing tight bands round the waist, either with or without corsets. With tight-lacing the edges of the ribs instead of sticking out press in and produce a furrow and the formation of fibrous tissue at that part. Thus a portion of the edge of the liver may be cut off from the main mass more or less completely by fibrous tissue. The lobe thus formed may become much thinned and flattened out and thus spread over a considerable portion of the right side of the abdomen. This flattening is probably effected to a great extent by the pressure of tightly laced corsets.

The important condition, and the one to which I particularly wish to refer, is that of wandering liver. Normally, the liver is held up by the tissue between a portion of posterior part of the upper surface of the liver and under surface of the diaphragm (the fixed part). This f a sort of triangular space which is surrounded by peritoneum as it is reflected from the upper of the liver to the under surface of the diaphragm. peritoneum around this space is called the coronary li and on each side the thicker double layers of peritoneum called the triangular ligaments. Then we have suspensory or falciform ligament running from the back the anterior abdominal wall in the middle line from the of the umbilicus upwards to the upper surface of the Its function is not so much to suspend the liver as to the right lobe sliding too much downwards and to the It is loose when the stomach is empty but becomes when the stomach is full and the liver is pushed towards right side. The round ligament which passes in the border of the suspensory ligament to the under surface of liver has also apparently much the same function. A important agent in keeping the liver in place is also the nexion with the vena cava and it is this which chie prevents the total descent of the liver and leads to t rotation. In fact, the rotation of the liver, to whi reference has been made in cases of hepatoptosis, occ around the vena cava. Among the other factors which ke the liver in its place is the negative intrathoracic pressu Once the liver is displaced downwards from the diaphrag it is sucked down still more by the atmospheric pressure a the intestines pass up between it and the diaphragm and a to the troubles of the patient.

Causation of hepatoptosis.—Those who have written on th subject have for the most part come to the conclusi that two factors generally come into play—viz., (1) so anatomical (? congenital) abnormality by which certain live are already ready to wander on suitable impulses; a (2) mechanical impulses, which, however, are not sudd but long-continued in their action. The supposed anatomic predisposition consists in some looseness or weakening of t fixation arrangements. Too long a coronary ligament h been suggested but not proven. Others think that the co nective tissue between the vena cava and the spine may looser than normal and allow of greater mobility. Other again, look on a congenital shortness of the round ligame as the chief agent. Langenbuch holds that this conditi begins, not as a descent of the liver from the diaphrag but as a rotation of the liver forwards around the vena cav This increases the tension of the round ligament and if th rotation is continued that ligament brings the liver near to the umbilicus, especially if the ligament is congenitall short. As the dislocation proceeds the suspensory ligame also becomes stretched. That the vena cava plays an important part is evidenced in some cases by disorder of th venous circulation. As the liver rotates around the vein pulls on it, shortens the intrathoracic portion, and may lea to such interference with the venous return that a capu Medusæ may form at the upper part of the abdomen. Th impulses which induce the descent of the liver are ver various and more or less long-continued. They are no sudden and severe injuries, otherwise we should expect th condition to be much more frequent than it is and mor common in men than in women.

Among the most important agents in leading to hepato ptosis are relaxation of the abdominal walls, as afte repeated pregnancies and the wrong use of corsets and band around the waist in connexion with tight-lacing or th support of heavy clothing. These points will be speciall referred to in speaking of enteroptosis and the remarks then made apply equally to the production of hepatoptosis Other causes which lead to descent of the liver in cases pre disposed to it are marked kyphosis and various conditions o the thorax—e.g., constriction of the thorax, pleural effusions long-continued cough and whooping-cough, emphysema o the lungs, &c.; also heart troubles, giving rise to increase size and weight of the liver, and so on.

Dr. A. Keith, in his excellent lectures on Enteroptosis, states that enteroptosis is due to the upsetting of the balanc between the inspiratory and expiratory muscles. He look on active contraction of the crura of the diaphragm as th most important factor. According to him there are two causes of displacement of the liver and the stomach—viz., relaxation or paresis of the abdominal muscles which maintain the shelf on which these organs are supported, and

---

[1] THE LANCET, March 7th (p. 631) and 14th (p. 709), 1903.

constriction of the abdominal cavity by clothing, or contortion by disease, preventing the forward rotation of these organs during respiration. Corsets, by pushing in the ribs, make the action of the costal fibres of the diaphragm more vertical and thus more active in pushing down the viscera.

Symptoms.—This condition of the liver is associated with enteroptosis, but apart from the symptoms due to that condition the dragging of the liver and the pressure caused by it in its new position must give rise to very great discomfort to the patient. The symptoms are often distractingly vague and as this condition is always associated with enteroptosis the indefinite symptoms which are there present are met with here also. Among them may be mentioned various gastric troubles. As the result of the displacement of the liver the pyloric orifice of the stomach may become pressed upon or kinked, with the result that dilatation of the stomach may ensue with various dyspeptic symptoms, vomiting, meteorismus, &c. The intestines which crowd up behind the liver may also become pressed on from time to time and much flatulent disturbance is thus caused. In addition, the weight of the liver and its presence in a faulty position give rise to much general abdominal discomfort, dragging pain, &c. Jaundice and gall-stone colic may also arise from kinking of the bile-ducts and gall-stones are not uncommon. Symptoms may arise also as the result of paresis of the intestine and circulatory disturbances.

The general symptoms are often extremely vague and it may be impossible to focus the trouble at any one part. There is pain practically all over the abdomen but it seems to radiate from the epigastric region. In a case on which I operated the pain at the lower pain of the abdomen was described as a dragging pain, while that at the upper part was more of a burning character, extending through to the back and upwards into the shoulders. The latter pain was much worse on lying down than on standing up. Reflexly there may be general nerve disturbances, such as hysterical attacks, giddiness, &c. There are frequently also marked loss of flesh, obstinate constipation, and sometimes mucous colitis.

The examination of the patient should be conducted both in the recumbent and in the erect posture. If the examination is limited to the recumbent position it may be that in the milder cases the liver completely recedes beneath the ribs and the condition is overlooked. When the patient is sitting or standing, however, the liver may be felt descending below the ribs or even forming a large tumour in the abdomen to the right side of the middle line, sometimes extending as low as the pelvis, and capable of being moved upwards and towards the right. The surface of this tumour is smooth, its sharp border may be detected, and also in some cases the gall-bladder. On percussion a very important point in marked cases is that the lung resonance merges into the intestinal resonance behind as the result of the intestines passing up behind the liver.

As regards the cases where a flattened lobe is formed that only occurs in grown-up women and there is a history of long-continued constriction of the waist, either with or without corsets, worst in cases where no corsets are worn The general symptoms are much the same as those just mentioned. In these cases the portion of the liver which is affected may be so thin as to produce no evidence of dulness on percussion and the edge may also be missed on examination. In fact, the more solid portion of the liver coming down beneath the ribs at each inspiration may be looked upon as the ill-defined margin of the liver.

Treatment.—The treatment of hepatoptosis is a very difficult matter. Usually it consists in a rest cure and in the employment of abdominal belts or bandages. These belts are of very doubtful value and this to some extent is due to the fact that they are applied while the patient is in the erect posture, that they do not come low enough, and are too tight at the upper part. Attempts have been made to support the liver by corsets or belts applied while the patient is in the recumbent position, especially tight around the pelvis, sometimes in addition with pads over the iliac fossæ, and loose at the upper part, the idea being to crowd up the intestines so as to diminish their drag and also to utilise them as a pad to support the liver and kidney. In mild cases a considerable amount of comfort may be obtained in this way and the patient may be content with the result, but in the more severe cases the relief obtained is comparatively slight. Hence the question of some possible operative measure has to be considered and I have recently in two cases made an attempt to fix the liver in its normal position by means of stitches and in both cases, at first at any rate, with remarkable relief to the patients. On looking up the literature I find that a few operations of this kind have been done but they are very few and apparently have not attracted much attention. In most of the cases in which the operation has been done benefit is said to have resulted.

The principle of the operations which I have done was to replace the liver in its normal position and to try to promote adhesions between it and the diaphragm. The replacement of the liver is sometimes a little troublesome unless one bears in mind the double deformity—namely, the descent of the organ and its rotation forwards In replacing it, therefore, the first step must be to rotate it backwards and to the right, and then, making sure with the finger that there is nothing between it and the diaphragm, to push it upwards and backwards into its normal position. The second aim of the operation—namely, the fixation of the liver in its normal position—is obtained in two ways. In the first place, it is desirable to get as broad an adhesion between the liver and diaphragm as possible and this I did in my cases by sponging the upper surface of the liver with undiluted carbolic acid so as to set up a certain amount of peritonitis and effusion over the greater part of the surface. With the view of holding the liver in its place while adhesion occurred several silk stitches were passed between the upper surface of the liver and the diaphragm. In the second case I first introduced a couple of silk stitches running from left to right high up on the upper surface of the liver, carrying them under the capsule of the liver for a distance of about one and a half to two inches in each case. One of these stitches was placed near the suspensory ligament and the other as far to the right as possible. The two ends were then passed through the surface of the diaphragm, taking hold of the muscular coat, and when these stitches were tied the liver was for the time retained in position. In addition, one or two vertical stitches were passed under the capsule in a similar manner towards the lower margin of the liver, the ends being brought out above and below the costal cartilages immediately over them, and these stitches were tied over the cartilages. Lastly, the free edge of the liver was stitched to the peritoneum and muscular walls of the abdomen along the greater part of its course. This fixation by stitches must be carefully and elaborately done because the liver is such a heavy organ that unless a good adhesion is obtained it will in all probability very soon break loose.

As regards the subsequent treatment. the patient should be kept in bed in the recumbent position for about six weeks and before she is allowed to sit up should be fitted with corsets which are laced up tight below and loose above so as to hold up the intestines. It may also be advisable to place pads over the iliac regions beneath the corsets so as to hold up the intestines still further, but these are not absolutely necessary if the corsets get a good hold of the lower part of the abdomen. These corsets will be again referred to in speaking of enteroptosis.

The suggestion has been made that the round ligament should be divided because it is held by some to play an important part in pulling the liver downwards and forwards. I did not do this, but in another case I should certainly examine the state of matters as regards this ligament and it could, of course, be perfectly easily divided if it were thought necessary.

The results in the two cases which I have had were in the first instance very good and in the last case, where greater care was taken in the procedure, the liver seems, for the present at any rate, to have retained its position. In this case, which was combined with marked general enteroptosis, I also stitched up the pyloric end of the stomach and the hepatic flexure of the colon to the under surface of the liver; but I did not deal with the moveable kidneys nor with the colon on the left side. When last seen the patient was complaining of discomfort and dragging pain on the left side, especially when and after the bowels act. This seems to be more especially referable to the descending colon and the loose left kidney. Whether these should be fixed also or whether suitable corsets would remedy matters it is difficult to say. I have not as yet been able to induce her to come into hospital again to have corsets fitted.

The conclusion I have at present come to as regards operation in cases of hepatoptosis is that, where it is necessary, careful stitching of the liver, with the subsequent use of Gallant's corsets, is all that is advisable in the first instance. Subsequent fixation of kidneys, &c., may be felt for future consideration. Where combined with marked enteroptosis further procedures to be mentioned presently may be required.

ENTEROPTOSIS.

The condition of descent of the alimentary tract, or enteroptosis, also often spoken of as Glénard's disease, is not uncommon and chiefly affects the stomach and the large intestine. It is frequently associated with moveable kidney and sometimes with hepatoptosis, probably more frequently with a slight degree of hepatoptosis than is quite realised. The inciting causes of this condition are various but the following are the two most important—viz., distension of the abdomen as in repeated pregnancies with consequent flaccidity of the walls and the management of the feminine clothing, especially the erroneous use of corsets. Hence it is that this condition is comparatively rare in men as compared with women. A pendulous state of the abdomen and separation of the recti is a very important factor. In these circumstances the intestines lose their natural support and are actually dragged down because no vacuum can be left. This drag will also tell on the liver and kidneys and thus a general descent of the abdominal organs is brought about. As regards the management of the clothes, the chief factor is the weight of clothing which is hung round the waist. The use of corsets is often blamed as the essential cause, but, while tight-lacing is no doubt a frequent source of trouble and may lead to flattening out of the right lobe of the liver, stretching of the omentum, &c., corsets when properly used are not without value. The great advantage of corsets is that they help to protect the abdomen from constriction by the tapes and bands used in suspending the nether garments. Where no corsets are worn and the garments are kept on in this way these bands and tapes are a fruitful source of trouble and probably do as much harm as tight corsets. Ladies who give up the use of corsets must suspend their garments over the shoulders. Apart from tight lacing the chief objection to corsets is their wrong application, especially in cases where there is a tendency to descent of the abdominal contents. Corsets are usually put on while the patient is in the erect posture and they are apt to be drawn too tight at the upper part. The former is a very important point in patients with a tendency to enteroptosis. If a patient suffers from hernia the rule is that before applying his truss he shall lie down, replace the hernia, and apply the truss while in the recumbent position; and the same rule should hold good in regard to putting on corsets in cases with a tendency to enteroptosis. If the corsets are put on and tightened up in these cases while the patient is in the erect posture the abdominal organs are hanging down and held in that position, and when the additional weight of the petticoats, &c., is added they are still more pulled down and the condition consequently aggravated.

The symptoms are of a similar character to those of hepatoptosis but on the whole they point more to the gastro-intestinal tract. Among these are chronic dyspepsia, pains in the epigastric region and between the shoulders and over the abdomen generally, chronic constipation often very marked, mucous colitis, often a marked neurasthenic condition, and loss of weight and strength. The whole condition is often most difficult to make out and the cases are frequently classed as abdominal hypochondriasis. The statements of the patient are very often inconsequent and so confused that one can make nothing out of them. The shape of the abdomen is very characteristic. Gallant[2] has made curves of the abdomen in these cases which show that while in the healthy abdomen in the erect posture without any clothing the point of maximum protrusion is above the umbilicus, in Glénard's disease the maximum protrusion is well below this point and there is a hollow above. In examining the abdomen in these cases he first measures the waist with the corsets and clothing on and then, having removed them, applies a band around the waist in the same position as the narrowest part of the corsets, tightening it up till the measurement is the same as before undressing. He is thus able to see what the exact change in shape is as influenced by the clothing and he finds a very remarkable increase in the protrusion of the lower part of the abdomen in these cases when the clothing has been put on. In the recumbent position in cases of enteroptosis the point of greatest prominence is above the umbilicus, while normally it is below. Beyond the general pendulous condition of the abdomen and its shape there is nothing much to be made out on examination, unless in cases where the liver, [illegible] kidneys, or spleen are also moveable.

As regards the treatment of Glénard's disease, Gallant lays down rules for the rest cure and for the use of corsets which he has devised and to which I have previously referred. His principle as regards the use of corsets is, in the first place, to allow the prolapsed viscera to resume their natural position by gravity, laying the patient upon her back in order that the organs may return to their proper position, this being facilitated by rubbing or stroking the abdomen. Secondly, while lying on the back, she is measured for a corset which must fit closely over the hips and suprapubic region, but must afford sufficient room above the umbilicus for the replaced colon and stomach. Thirdly, when putting on the corset the patient places it around her waist, lies down upon the bed or couch, flexes her knees, and raises her hips, so as to further the visceral replacement and, while in this posture, fastens the corset, beginning from below upwards. Fourthly, in lacing the corset two strings are used, one beginning at the bottom and lacing up to the first eyelet below the waist line, and this lace must be drawn as tightly as can be borne; the second begins where the lower one leaves off and is laced up to the top and must never be drawn tight. Any tendency of the corset to ride upwards indicates that it has not been laced tightly enough below the waist, or that it has been laced too tightly above, or that the corset is too large. With this corset Gallant states that belts, binders, and pads can be done away with. In some cases pads may be placed in each iliac fossa below the corsets, especially where the patient is spare. In others a broadish band may be tightly buckled around the lower part of the corset.

Various surgical operations have been suggested in these cases but they are not always satisfactory. Gastroplication has been suggested, but its value is very doubtful. Gastro-enterostomy has also been employed with temporary advantage. Suturing the prolapsed stomach to the abdominal wall has been done with relief in some cases. Shortening the gastro-hepatic omentum, thus leaving the stomach mobile, is said to have done good. In my case I not only fixed the liver but also attached the hepatic flexure of the colon and the pyloric end of the stomach to the under surface of the liver. The subsequent course of the case rather implies that the splenic flexure of the colon might with advantage have been fixed also, but that would mean a fresh incision with consequent prolongation of the operation. Fixation of the liver itself has been already mentioned. Suture of the abdominal walls where the recti are separated, thus relieving the weakness of the abdominal wall and the pendulousness of the abdomen, has also had good results.

Of these various measures, in cases where there is no hepatoptosis I should say that shortening the gastro-hepatic omentum and suturing the abdominal walls and the subsequent use of Gallant's corsets would be the most satisfactory method of procedure. Where hepatoptosis is present the liver should also certainly be fixed. The question of fixing the kidneys or colon might be left till the result of the former operations and of the use of the corsets is seen.

LONDON HOSPITAL MEDICAL COLLEGE.—The following sums have been received during March for the Endowment Fund of this College: Anonymous, through the Hon. Sydney Holland, chairman of the London Hospital, £500; Mr. E. P. Thompson, £100; and Mr. Martin Sutton, £5 5s. In addition the anonymous donor has promised a further sum of £1000 provided an additional sum of £5000 be obtained by August 1st from others. It is earnestly hoped that by the kindness and liberality of those who know the London Hospital Medical College and the excellent work carried on there the required amount may be forthcoming by that time.

THE AMERICAN MEDICO-PSYCHOLOGICAL ASSOCIATION.—The sixty-second annual meeting of the American Medico-Psychological Association will be held at Boston, Massachusetts, from June 12th to June 15th inclusive. The address of welcome will be given to the association by Curtis Guild, Governor of the Commonwealth of Massachusetts. A number of papers will be read and a symposium on dementia will be held. On Jan. 16th the members of the council of the association held a meeting in New York City, where resolutions expressive of the regret of the association at the death of Dr. Emmet Cooper Dent, the late secretary, were directed to be forwarded to the family of Dr. Dent.

The Lumleian Lectures

ON

TABES DORSALIS.

Delivered before the Royal College of Physicians of London on March 22nd, 27th, and 29th,

BY DAVID FERRIER, M.D. EDIN., F.R.S.,

FELLOW OF THE COLLEGE, PROFESSOR OF NEURO-PATHOLOGY IN KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE HOSPITAL; AND PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE, BLOOMSBURY.

LECTURE II.[1]

Delivered on March 27th.

MR. PRESIDENT AND GENTLEMEN,—In health the centrifugalised deposit from the cerebro-spinal fluid contains scarcely any cellular elements beyond an occasional endothelial cell and perhaps from one to three lymphocytes in a field with a magnification of 400 diameters. In certain diseases the cellular elements are present in excess. In acute microbic affections of the cerebro-spinal meninges, as by staphylococcus, pneumococcus, and diplococcus intracellularis, a leucocytosis occurs in which the leucocytes are of the polynuclear type. On the other hand, in certain chronic affections of the meninges—syphilitic, tuberculous, &c.—an excess of leucocytes also occurs These are of the mononuclear type—in other words, there is a lymphocytosis. It has been shown by Widal, Sicard, Ravaut, and others, and their observations have been confirmed by my own and Purves Stewart's investigations, that in tabes, as well as in general paralysis of the insane, from the earliest to the latest stages there is a marked lymphocytosis of the cerebro-spinal fluid. I have in several instances relied on this lymphocytosis as establishing the diagnosis of general paralysis before there were any abnormalities of the pupils or other physical signs characteristic of the disease. In a case of tabes or general paralysis, instead of two or three as in the normal state, one may count a hundred or even several hundred lymphocytes in the field of the microscope. At first sight this lymphocytosis would seem to confirm the views of those who ascribe the disease to a syphilitic affection of the meninges, either generally, or of Nageotte's meningeal root sheath, or of the posterior lymphatic system of the spinal cord, as maintained by Marie and Guillain. But lymphocytosis occurs in other affections in which meningitis, syphilitic or otherwise, plays no part. Thus it has been found in Landry's paralysis, in the subacute combined degeneration of pernicious anæmia (Purves Stewart), and in herpes zoster (Sicard). Lymphocytosis cannot, therefore, be regarded as pathognomonic of meningeal inflammation, though no doubt meningeal inflammation would accentuate it. But the most powerful argument against the syphilo-meningeal origin of the lymphocytosis in tabes and general paralysis is the fact that it does not yield in the slightest degree to the most energetic anti-syphilitic treatment (Milian, Purves Stewart). In active syphilitic lesions of the nervous system, however, the lymphocytosis that may be present tends to disappear in the course of treatment, as I show on the screen from a case of syphilitic paraplegia under the care of Purves Stewart. After a month's antispecific treatment the lymphocytes had decreased from 52·6 to 16·1 per field and the symptoms had become greatly ameliorated.

Having thus passed in review the different theories which have been advanced in reference to the pathogeny of the tabetic degeneration we have seen that there is not one which is not open to several more or less serious objections. Instead of attempting to be more precise than the facts permit I am inclined to adopt the hypothesis of Thomas and Hauser that the essential lesion of tabes is a dystrophy similar to that induced by certain toxic agents, affecting the sensory proto-neuron as a whole and manifesting itself in degeneration both of the peripheral and central terminations, of which the intermedullary are the more vulnerable, and are usually the earliest to exhibit anatomical change. The process, however, is not confined to the spinal proto-neuron but may affect among others the optic, the sympathetic, and certain motor neurons. And here I would express, in concurrence with Fournier, Mott, and many other neuropathologists of the present day, my belief in the essential pathological identity of tabes and general paralysis. They are, in my opinion, merely different aspects of the same polymorphic disease. One cannot say that they are the same disease so far as their clinical manifestations and course are concerned, any more than one would say that tuberculous meningitis and pulmonary consumption are the same. But the morbid process underlying both is identical. Both are tabetic or wasting affections—of the sensory proto-neuron in the one case and of the cortical neurons in the other. The essential etiological factor is, as we shall see, the same and the date of development of the two affections after the primary infection corresponds. No blind or crude primary meningeal inflammation could selectively attack only such regions—the fronto-parietal by preference—as exhibit the atrophic cortex and adherent lepto-meninges characteristic of general paralysis.

The primary lesion in general paralysis, as in tabes, is a dystrophy of the neurons and their connexions, the sclerosis, thickening of the membranes, and walls of the blood-vessels being only a secondary result of the parenchymatous degeneration. Not infrequently tabes and general paralysis are combined or succeed each other in the same individual. Clinically some of the characteristic signs, notably the Argyll-Robertson pupil, are common to both, and in both there is the same cerebro-spinal lymphocytosis. It would, in my opinion, conduce to a truer conception of the pathology of these affections if we were to call them both by the generic name tabes, classifying them specifically as cerebral tabes (general paralysis), spinal tabes (tabes dorsalis, locomotor ataxy), and cerebro-spinal tabes (so-called tabo-paralysis) according as the disease affects the brain or spinal cord, or both conjointly.

ETIOLOGY OF TABES.

Up to 1876, when Fournier first pointed out the great frequency of antecedent syphilitic infection in tabes and indicated their probable causal relationship, tabes was most commonly attributed to sexual excess or the complex of injurious influences associated with exposure to cold. The supposed causal relationship between sexual excess and tabes was probably only a damnosa hereditas from the tabes dorsalis or sexual neurasthenia of the Hippocratic writers.

Sexual excess, like all other debilitating influences, may be placed among the exciting causes and many tabetics have probably exhausted themselves in this way, but the influence of sexual excess in the causation of tabes has been greatly over-estimated and if that were the only cause the disease would certainly be much more common than it is.

Similarly as regards cold, or damp cold which Romberg thought, and which is still regarded by von Leyden as one of the principal causes of tabes, this is probably founded more on the patient's belief that his tabetic pains are rheumatic in character and that he must have caught a chill, slept in a damp bed or the like, than on any more substantial basis. When we consider how often when our etiology is at fault, not only in respect of diseases of the nervous system but many others, it has been the custom to fall back upon exposure to cold as the probable cause, afterwards proved insufficient, we may without undue depreciation call it the last refuge of destitute etiology. Like sexual excess, exposure to cold and damp would, without doubt, have an injurious influence and probably excite or intensify tabetic symptoms already incipient, so that the patient might have some grounds for ascribing his malady to this cause. But that exposure to cold by itself is a sufficient cause of tabes is, in my opinion, a mere vague assertion, supported by no accurate data, and at variance with one's daily clinical experience. A history of exposure to cold is not found more frequently in tabes than in many other affections of the nervous system.

Fournier's views as to the causal relationship between syphilis and tabes were at first received with scepticism, not to say strong opposition, in many quarters; and the frequency of antecedent syphilitic infection in the personal history of the tabetic was not regarded as more than might be found in other forms of disease of the nervous system. But Fournier's views soon gained powerful support, among the first by Gowers in this country and by Erb in Germany; and Erb who at one time (1878) was a strenuous opponent, is now perhaps the most eminent advocate of the syphilitic origin of tabes. It is now so generally admitted by neuropathologists, with some few notable exceptions, such as von Leyden, that syphilis is the principal cause of tabes, that it seems unnecessary to quote the data on which this opinion is based. But as the elimination of cause and effect depends for the present mainly on the statistical method and as this is liable to many fallacies, depending on the personal equation of the observers and the material dealt with, it will be sufficient to state the results obtained by Erb, whose probably unequalled experience and laborious inquiries carried out with systematic uniformity invest his inductions with exceptional value. In the most recent of his numerous contributions on this question Erb states that among 1100 cases of tabes occurring in his own practice among men of the better class—and therefore better witnesses than those living among poor and squalid surroundings—89·45 per cent., or practically 90 per cent., had had chancre or syphilis, and only 10·54 per cent., or practically 10 per cent., had not been ostensibly infected. But of these, in only 3 per cent. was it impossible to find any ground for suspecting an antecedent syphilitic infection.

---

[1] Lecture I. was published in THE LANCET of March 31st, 1906, p. 881. The bibliography will be given at the end of the lectures. (The lecture was illustrated by lantern slides.)

Now contrast the above statistics obtained from 1100 tabetics with those of 10,000 cases, also of men of the better class, of all varieties of disease, excluding tabes. Of these only 21·5 per cent. had had syphilis, as against 89·5 per cent. among the tabetics—i.e., that syphilis was found 4·5 times more frequently among tabetics than among other patients. Similar investigations among 158 tabetic men of the lower orders give a somewhat lower percentage of antecedent syphilis—viz., 77·2 per cent., but among 1300 non-tabetics only 6 54 per cent. had had syphilis as against 93·46 non-infected.

Among women, who are less liable to tabes than men and those of the better class less so than those of the lower orders, it is for various reasons much more difficult to determine the question of syphilitic infection. But Erb found that among 15 tabetic women of the better class at least 86·7 per cent., and probably 93·3 per cent., had been infected. Among 16 women of the lower orders, however, syphilis was probable in only 68·7 per cent. and unproved in 31·3 per cent. Taken altogether a statistical inquiry among 1321 cases—viz., 1100 men of the better class gives 89·5 infected; among 158 men of the lower class, 77·2 per cent.; and among 63 women, 80 per cent. as probably infected. Essentially the same is true of general paralysis.

So far for mere statistics: the general result being that in about 10 per cent. of the cases syphilis is unproved. These 10 per cent., however, constitute the pivot round which the essential question turns, whether tabes, like diphtheria or tuberculosis, is always due to a specific infection or whether it may result from some other cause. This is not a mere academic question but one of far-reaching practical importance. Can we in the present state of our knowledge give a definite, or approximately definite, answer to it? We may perhaps do so by taking other facts into consideration besides mere percentages. It has been established, and is generally recognised, that tabes frequently follows syphilitic infection of a mild type and therefore more likely to escape notice, particularly among those in whom personal cleanliness is not a cardinal virtue. And syphilis ignota or occulta is familiar to syphilologists and dermatologists. Some noteworthy investigations on this point have been made by Hirschl the results of which are worth quoting. He found that of 63 patients suffering from gummatous affections of indubitable syphilitic origin, in only 54 per cent. was there a certain history of syphilis, in 9·5 per cent. it was probable, while in 36·5 per cent. no evidence, other than the patient's actual state, was forthcoming of syphilis, hereditary or acquired. Practically the same results were obtained in reference to general paralysis. Similar statistics to those obtained by him in reference to syphilis and tabes have been quoted by Gowers as having been arrived at by G. Pernet of University College Hospital in reference to syphilitic affections of the skin. Syphilis could only be proved in 80 per cent. of the cases. One may therefore say with justice that the syphilitic origin of tabes and general paralysis is statistically just as well proved as that of gummatous affection of the skin.

Apart from juvenile tabes, which is always syphilitic, hereditary or acquired, and which affects both sexes in same proportion, tabes occurs most commonly among men from 30 to 40 years of age, and on the average from seven ten years after the primary affection. There are, however, exceptions to this rule, and I have seen it develop in a man 70 years of age, some 40 to 50 years after infection with syphilis. And there is a case on record (Berger) of a aged 74 years becoming tabetic after syphilitic infection the age of 70 years. Tabes at from 30 to 40 years of age is significant harvest of the wild oats sown some ten previously, and the classes who sow wild oats most freely are those who reap tabes most abundantly. Towns furnish more cases of tabes than those who live in the country, and great centres of population with their greater risks and temptations more than the smaller. Tabes general paralysis are rare among priests, and of these only such as have had syphilis or exposed themselves to it (Bouchard).

Tabes is less common among women of the better class than among those of the lower; doubtless, as Moebius has suggested, owing to the fact that men of the better class less frequently marry while still suffering from infective syphilis. But conjugal tabes is not uncommon and most neurologists have seen examples of this. Among others, Mott has given several interesting illustrations. Almost without exception there has been syphilitic infection (from 90 to 96 per cent., Hudovenig) on one side or the other; usually the husband has infected the wife. Nonne has related a very remarkable family history. A child, aged five years, was infected with syphilis through sleeping with a syphilitic bedfellow. At the a of 18 years he became tabetic. The child infected t mother and the mother the father. Both these becam tabetic. In another family, described by Souques (quoted Erb), the father was syphilitic and became a gener paralytic; the mother became tabetic, and two you daughters also showed signs of tabes—four in one famil Many similar cases might be quoted in detail, but it is u necessary to multiply them. Syphilis, acquired or heredita was the common factor in all. And the question has be mooted (Lavalle, Moebius, Erb) whether there may not be form of the syphilitic virus falling with special inciden on the spinal and cerebral centres and leading in due cour to tabes or general paralysis. Thus Brosius relates t remarkable history of seven glass-blowers who were infecte in the mouth from the same source in 1891. All were treate for syphilis and dismissed as cured after a few weeks anti-specific treatment. In 1902—i.e., after 12 years—fi of them came under his observation again. One was tabeti the second had signs of general paralysis; the third w already a marked general paralytic; the fourth had Argyl Robertson pupils and indications of so-called tabo paralysi while the fifth at the time of examination was still in go health. The other two had not been traced. The onl common factor in all these cases was the syphilitic infectio

It has been shown by Krafft-Ebing that general paralyti are insusceptible to inoculation by the syphilitic virus. Th is a negative fact of great significance and of much m importance than if the converse were true, for re-infect is always a possibility. Whether the same holds in resp to tabetics has not so far as I know been yet demonstrated but it is more than probable. Who has ever seen a tabet with a primary sore or even with secondary symptoms? considerable number, both during life and after deat exhibit tertiary manifestations or traces of antece syphilitic lesions. But these date from the which preceded the tabes. Yet it cannot be said tabetics do not run the risk of re-infection, for it notorious that in the pre-ataxic stage tabetics frequent exhibit excessive erotic propensities and expose thems freely to the possibility of acquiring syphilis.

Female children apart, tabetic *virgines intactæ* are *ares*. They are, however, not unknown. Of two of whom have read, the one (reported by Nonne) was a tabetic gi aged 20 years, who was infected in infancy by her mot suckling a syphilitic foster-child at the same time; t other (described by Erb), a virgin, aged 36 years, who time previously had had a chancre on her lip.

One might multiply arguments in favour of the relation between syphilis and tabes but they are unneces For those above related, singly and collectively, leave in opinion little room for doubt that tabes and general paraly are in all cases syphilitic and that tabes *per se* is as much proof of syphilis as a gumma of the skin. Those who may still unconvinced and seek a more positive sign will probably have to wait till in some pathological laboratory a monkey will be exhibited inoculated with a virus of syphilitic origin (a product, perhaps, of the spirochæta pallida) showing Argyll-Robertson pupils and loss of knee-jerks and the question of the syphilitic origin of tabes will be solved by the walk of a tabetic chimpanzee.

It has been urged by von Leyden and Goldschneider as an argument against the syphilitic origin of tabes that the disease is rare among prostitutes, among whom nevertheless syphilis is rife. But it must be remembered that tabes is less common among women than men and one must also take into account the fact that as tabes is a late manifestation of syphilis it is not to be expected among those who are still young enough to ply their wretched calling. This accords with the statistics of Kron who, though he found no case of tabes among 148 young prostitutes, yet among 36 over 25 years of age found five, a large percentage enough.

Similarly it has been contended that in certain countries and among certain races tabes is rare, though syphilis is common. Thus, it has been asserted that in Bosnia and Herzegovina, in Japan, in Abyssinia among the Arabs, and among negroes tabes does not occur. But more accurate investigations have proved this assertion to be unfounded For tabes is common enough in Japan (Nose); it is not unknown in Bosnia and Herzegovina; it is as common in Abyssinia as in Vienna (von Halban); and it certainly occurs among negroes (Collins Hecht). It may not be so common among primitive races as among those more advanced in civilisation and all that this connotes, but this is not the point. The fact that tabes only occurs where infection with syphilis is possible is the essential point in this relation. If tabes can be shown to exist or to have existed in any land or people among whom syphilis has never entered and who have never had communication with any outside syphilised world, the exclusively syphilitic origin of tabes will have to be abandoned, but not till then.

The relative infrequency of tabes among those who have suffered from syphilis—it has been variously calculated at from 1 to 5 per cent. of the whole—is no argument against the syphilitic origin of tabes. For there are many affections due to syphilis—such as aortitis, hepatitis, and orchitis—which are relatively rare. And, as Erb remarks, the fact that perhaps only 1 in 10,000 of those infected with tubercle suffers from Addison's disease does not disprove the tuberculous nature of the affection of the suprarenal capsules. But the smallness of the percentage, as well as other considerations, suggests that in addition to syphilis there may be some predisposing or other coöperating causes determining the incidence of the syphilitic virus on the nervous system, and the development of tabes either of the brain or spinal cord, or both.

Heredity, as such, plays no part in the etiology of tabes, though as we have seen juvenile tabes indicates a syphilitic inheritance.

Mention has already been made of sexual excess and cold, to which great, but as we have seen undue, prominence has been assigned by certain physiologists. The same may be said of neuropathic inheritance to which great importance was attached by Charcot. It is not more frequent in tabes than in other forms of nervous disease. Some facts, however, suggest that certain families are specially prone to develop tabes and several instances might be quoted of more than one member of the same family becoming either tabetic or general paralytics after acquiring syphilis.

Certain malformations, or developmental anomalies, such as heterotopia spinalis, have been recorded by several observers (Mott, Orr and Rows, Rebizzi) in the spinal cord of those affected by tabes or general paralysis. All these have, no doubt, their significance, but they are by no means constant nor are they even common.

The view that the substratum of tabes lies in some defect of development, or vice of inheritance, which predisposes to premature decay of the essential elements of a highly specialised tissue and reversion to those of a lower type, so that certain individuals are, as it were, predestined to tabes, reaches its culmination in Benedikt's burlesque "Tabicus nascitur; non fit"! No one who has had experience of tabes in all ranks, and has seen among its victims numbers of men of the most healthy stock and vigorous physique, can regard it otherwise than a gross libel to speak of tabetics in general as being "connective-tissue individuals" (Bindegewebs-Individuen) or "degenerates" in any true sense of the term.

Among other exciting causes of tabes injuries have been blamed and many cases of so-called traumatic tabes have been put on record. There is no doubt that in certain instances—perhaps 5 per cent.—tabetic symptoms have first made themselves manifest after injuries of the spine or other parts of the body, and the limb injured has not unfrequently been the primary or principal seat of the characteristic pains. But a critical examination of such cases of Hitzig and others has failed to substantiate the efficacy of trauma as a cause of tabes independently of antecedent syphilitic affection.

Of greater importance perhaps than any of the above-mentioned exciting or coöperating causes of the tabetic degeneration is the influence of over-exertion or of over-exertion in debilitated states of the system. The principle underlying these degenerations is that the normal equilibrium between waste and repair which characterises health is disturbed and that in consequence of the process of waste exceeding that of repair the neurons, especially those most engaged, tend to break down and show dystrophic change. Edinger and Helbing have found that in rats artificially rendered anæmic, which have been compelled to work in a treadmill, or by other device to engage in long-continued muscular exertion, the posterior roots and posterior columns of the spinal cord exhibit degenerations similar to those of tabes. These facts are suggestive and appear to harmonise well with the views of those who regard fatigue and over-exertion as the most important causes of tabes. As coöperative causes certainly but not apart from syphilis, for the same degree of fatigue and over-exertion which may excite tabes in one in whom the soil is already prepared by syphilis may be borne by thousands of others without material damage.

Edinger's "compensation theory" (Ersatz-Theorie) seems also to afford a plausible explanation of the incidence of the affection in the parts most subjected to continuous strain, the most common being the sensory apparatus concerned in coördinated locomotion and maintenance of equilibrium. Occasionally, however, as in cervical tabes, the arms for similar reasons are more especially affected and the pupils and optic nerves would in like manner probably suffer more readily than any of the other organs of special sense. So also muscular atrophies would be more prone to occur in the muscles which are most taxed, similar to the occupation muscular atrophies of blacksmiths, railway porters, and the like. Probably the same principle may serve to explain the incidence of the tabetic degeneration, in one case on the brain and in another on the spinal cord. Raymond has related an interesting narrative of two brothers, similarly constituted by inheritance, who both became infected by syphilis about the same age. The one who lived a fast life and indulged in sexual excess became a tabetic; the other who exhausted his brain in the struggle for existence became a general paralytic. Facts like these are of eloquent significance. The sensory neurons and posterior columns of the spinal cord appear to be specially vulnerable to certain toxic agents. Whether this can be explained on evolutional or developmental principles; or more mechanically by peculiarities in the lymph circulation in the posterior roots and posterior columns; or by an elective affinity of certain poisons for special structures, such as nicotine for the cells of the sympathetic ganglia, is a question for the future. But degenerations similar to those of tabes have been shown to occur from poisons introduced from without, or generated within, as well as in the course of cerebral tumours, in some more obscure manner.

In the great epidemic of ergotism which occurred in Hesse in 1880 Tuczek observed many cases of so-called ergotin-tabes in which, following the preliminary acute gastric and other constitutional disturbances, paræsthesiæ and ataxic symptoms set in, sometimes several months after the ingestion of the poison. Occasionally there was a tendency to relapse, even when no further use was made of the poisonous grain in the dietary. These ataxic and sensory symptoms were found to coincide with degenerative changes in the posterior roots and posterior columns similar to those of tabes, differing only in their acute course and in the absence of sclerotic shrinkage. Lissauer's zones, however, remained intact and there were no pupillary symptoms. Somewhat similar degenerations, but less strictly confined to the posterior columns, have been observed in pellagra, endemic in certain districts, especially in Northern Italy, and due to the consumption of poisonous maize. The degenerations in this case affect not only the posterior columns, particularly that of Goll, but also the antero-lateral and pyramidal tracts. The exact nature and localisation of these degenerations are, however, not as yet precisely determined. So also in lathyrism, caused by the seeds of the lathyrus sativus, degenerations occur in the spinal cord, and a large number of inorganic poisons, which specially cause peripheral neuritis, also occasionally lead to degeneration of the posterior roots and posterior columns, such as alcohol, lead, arsenic, and some others.

Many of the organisms which are the cause of certain epidemic and endemic diseases, such as those of diphtheria, beri-beri, and lepra, generate toxins which not only induce multiple neuritis but also in some instances degeneration in the posterior roots and in their intramedullary processes and collaterals. Whether these degenerations are primary or secondary to the peripheral neuritic processes or whether the two are simultaneous is a question on which it is impossible at present to pronounce definitively. Further, and perhaps of greater significance in reference to the pathogeny of tabes, it has been shown that in certain cachectic states of the system such as pernicious anæmia (Lichtheim, Minnich, and others) and diabetes (Fischer, Williamson, and others), probably by the autochthonous development of toxins, degenerations occur in the spinal cord, especially in the intramedullary processes of the posterior roots, and tabetic-like symptoms ensue in the form of paræsthesiæ, pains, and ataxic disorders. But however much these toxic affections resemble tabes they are in reality only pseudo-tabetic and none of them conforms in its clinical history, course, and termination to tabes properly so called. Though weeks or even months may elapse before the poisons introduced into the system or engendered in it by the specific organisms produce their deleterious effect on the nerves and nerve centres, and though relapses may occur, there is a direct continuity between the introduction of the poison and the development of the symptoms, which run their course and cease when the virus is exhausted. In none of them do years elapse between the original infection and the commencement of the symptoms and none has the progressive character of true tabes. In none of them do the children suffer like the juvenile tabetics "who have their teeth set on edge because their fathers have eaten the sour grapes" of syphilis. The similarity, however, between the degenerations caused by these poisons and those of tabes strongly supports the hypothesis, originally advanced by Strümpell, that the tabetic degeneration is due to the action of a toxin of syphilitic origin. The tabetic degeneration is, as we have seen, a parenchymatous dystrophy, and has none of the features usually considered characteristic of tertiary syphilitic lesions. There are no cellular infiltrations, no specific vascular or gummatous changes, and it does not yield to the usual antispecific remedies. Hence it has been customary to term the lesions of tabes parasyphilitic (Fournier) or metasyphilitic (Moebius) manifestations. It may be said, however, that this is a mere *petitio principii* and that we have no certain criterion of what constitutes a syphilitic lesion. The spirochæta pallida has not yet been shown to be present in tertiary syphilis. But in any case it would be incorrect to term a state of abiotrophy (Gowers) or defective nutrition a positive lesion. For this reason Lesser's term "quartary syphilis," however appropriate to certain late manifestations of syphilis in the liver and other organs, is not strictly applicable to a condition in which parenchymatous dystrophy precedes the development of the sclerotic process.

The most probable pathogeny of the tabetic degeneration, therefore, is that it is the result of a toxin generated or conditioned by the syphilitic virus. But this is at present a pure hypothesis and one which has to surmount great difficulties. Even if, like the diphtheritic neurotoxin, it may be the product of the action of the specific organism on the proteids of the body, or set free in the elaboration of protective antitoxins, that it should take so long to develop, or lie dormant for so many years before exhibiting any signs of activity, is unlike anything that we know of organismal toxins. There is no para- or meta-syphilitic cerebro-spinal lymphocytosis as such apart from the commencement of the tabetic process and this is a fact of great importance. Dr. Purves Stewart, who has made investigations for me on this point, found that in a series of 12 cases the average number of lymphocytes in the centrifuge deposit of the cerebro-spinal fluid in secondary syphilis was 2 7, while in tertiary syphilis it was 0·9, or not more than the normal. The tertiary cases with active cutaneous lesions in progress had more lymphocytes, than the others, but even these were less than the average of the secondary cases. The lowest count in tabes, however, was 45. Most were between 80 and 100, while the highest was 316 in the same relative field. And even if we were to consider it possible that there might be long years of apparently normal health in spite of the presence of some malignant toxin in the system, we have to reckon with the fact that the tabetic process once begun is essentially of a progressive nature and postulates a more or less continuous generation of the poison.

In this relation mention may be made of the researches of Ford Robertson, McRae, and Shennan. These observers have found a bacillus closely resembling the Klebs-Löffler bacillus of diphtheria in cultures from the walls of the respiratory, gastro-intestinal, and genito-urinary tracts of patients dying from general paralysis and from the genito-urinary tracts of general paralytics and tabetics during life. Rats fed on broth cultures of this diphtheroid bacillus became ill after some weeks, and when killed showed, in addition to signs of gastro-enteritis, acute degenerative changes in the cortex cerebri, resembling to some extent those of general paralysis, as well as degenerative changes in the cells of the spinal cord. These observations are of much interest, but a definite causal relationship between this bacillus and tabes or general paralysis is far from being established; for the same bacillus was found by them in the genito-urinary tract in ten out of 14 patients suffering from forms of insanity other than general paralysis.

[*Note.*—I had written this before Dr. W. Ford Robertson had delivered his Morison lectures on the Pathology of General Paralysis, now in course of publication, and I am indebted to him for allowing me to read the manuscript of those as yet unpublished and to examine some of his microscopical preparations. He holds that general paralysis is the result of a bacterial toxic infection from the respiratory and alimentary tracts owing to the impairment of the resisting power of the organism by syphilis, alcoholism, or the excessive use of nitrogenous foods. The bacillus has the cultural and morphological features, and reaction to Neisser's stain, of the Klebs-Löffler bacillus, of which it is an attenuated, or more probably a special form, to which he gives the name, bacillus paralyticans. The bacillus is polymorphic, and *among other* characters which distinguish it from the xerosis bacillus and Hoffmann's bacillus is its power of forming acid when cultivated in glucose broth. The leucocytes of the blood of the general paralytic, he maintains, have a greater dissolving power over these bacilli than those of *normal blood*, and *the serum is also more* lysogenic. These diphtheroid bacilli, more or less altered by lysogenic action, have been found by him and his colleagues in the catarrhal pneumonic foci of general paralytics, in the adventitial spaces of the cerebral vessels, and in the meshes of the pia-arachnoid. *They have also been found in the* blood, in the centrifuge of the cerebro-spinal fluid, and in the urine of the general paralytics, especially during congestive attacks. From these fluids cultures of the bacilli have been obtained when sufficient time has been allowed to destroy the *phagocytic or lysogenic action of the blood.* Rats infected, or fed, with cultures of these bacilli showed changes in the cerebral cortex suggestive of those of general paralysis and similar appearances were also found in a goat which had ingested them. He considers that in general paralysis there *is a life-and-death struggle* between the leucocytes and the diphtheroid bacilli in which the leucocytes succumb. There is a bacillary invasion. Most of those which reach the blood are digested but many escape from the circulation, either through the capillaries of the kidneys or through the walls of the cerebral blood-vessels into the adventitial lymph channels. The further disintegration of the bacilli in these lymph channels gives rise to a local toxic action in addition to the general toxæmia. The special cause of the cord lesion in tabes is probably the absorption of toxins from some peripheral septic focus, such as the bladder.

Interesting as these views are there are many difficulties in the way of their acceptance as a satisfactory pathogeny of tabes, cerebral or spinal. Eyre and Flashman as the result of examination during life of the throats of large numbers of patients suffering from different forms of insanity, as well as of the tissues of a considerable number of cases post mortem, could not determine *any greater* incidence of diphtheroid organisms in the throats of the insane than of the sane and found no evidence that the bacillus diphtheriæ is more common in the throats of general paralytics than of other insane patients. Of ten cases of general paralysis examined post mortem, diphtheroid organisms were found in the respiratory tract in four; and the same number in 26 cases of other forms of insanity. They were unable to trace any causal connexion between the bacillus diphtheriæ and general paralysis of the insane.

I have the authority of Dr. W. Bulloch, one of our eminent bacteriologists, for the following remarks: Diphtheroid organisms are ubiquitous both in health and disease. They may be found in the intestines, in the genito urinary passages, in the throat, in the nasal secretions, and elsewhere in perfectly normal people, as well as in catarrhal conditions of the respiratory tracts.

[The characters given by Ford Robertson are not sufficient to distinguish his bacillus paralyticans from other forms of diphtheroid organisms. The formation of acid grown in glucose broth is not special to the bacillus paralyticans, for this is possessed in different degrees by various other diphtheroids. If diphtheroid bacilli can be found in the blood films of living general paralytics then general paralysis must be regarded, not as a toxæmia, but as a form of septicæmia ranking with relapsing fever as regards the dissemination of the organisms. If diphtheroid bacilli exist in the blood or cerebro-spinal fluid of general paralysis, they should be capable of cultivation at once without waiting for the cessation of any supposed bactericidal action, for no lysogenic action of the serum for bacilli of this group has been proved to exist. Specimens of the cerebro-spinal fluid, blood, and urine of several cases of tabes and general paralysis have been cultivated for me by Dr. W. d'E. Emery of King's College Hospital and by Dr. Bulloch, and have proved absolutely sterile. Ford Robertson emphasises the fact that he finds bacilli particularly after so-called congestive attacks. It is not improbable, therefore, that the bacilli which he has found so largely diffused throughout the tissues in general paralysis are only the results of a terminal invasion.

In order to establish any causal relation between the bacillus paralyticans and tabes it would be necessary to show that a toxin prepared from these bacilli can produce the symptoms and post-mortem appearances characteristic of tabes, cerebral or spinal. Such evidence Dr. Robertson has not produced. The experiments on rats related by him are not convincing, for it has been found by other bacteriologists that rats are almost immune to the most virulent form of the Klebs-Löffler bacillus. In presence of these and other considerations we may therefore say that the diphtheroid-bacillary origin of the tabetic toxin is at least not proven.]

In the absence of any living organism capable of generating a tabetic toxin it may be that the syphilitic virus under certain conditions so affects some viscus or gland that in time it develops and continues to elaborate some toxic internal secretion which exerts its noxious influence on the nervous system. In view of the brilliant therapeutic triumphs of the present day it is not, I think, too optimistic to hope that with the progress of bio-chemistry we may yet discover the source of the tabetic toxin, its nature, and the means of neutralising it and staying its ravages. We cannot expect to repair damage already done, for intramedullary degeneration is irreparable, but we may at least succeed in arresting the disease. This not infrequently happens spontaneously; and the therapeutic measures last employed are likely to get the credit of the happy result. But beyond palliation, or the temporary relief of urgent symptoms, no remedy, chemical or physical, has as yet been discovered which materially influences the morbid process. Antispecific treatment may be of service against possible coincident tertiary lesions, or may even cure pseudo-tabetic syphilitic symptoms; but certainly ordinary antispecific treatment exerts no beneficial influence on true tabetic degeneration and may, if carried to extremes, prove positively harmful. If, however, we believe, as I think we must, that the syphilitic virus is the *sine quâ non* in the etiology of tabes it ought to be our endeavour to combat this with all the resources at our command.

The comparative mildness of the primary constitutional symptoms in those who ultimately become tabetic would almost seem to indicate than when the syphilitic virus expends itself in severe primary and secondary manifestations there is less tendency to the subsequent development of the subtle poison which proves so disastrous to the nervous system. This mildness of the primary symptoms without doubt leads in many cases to insufficient treatment. Even the most efficient antispecific treatment, however, may fail to prevent the subsequent development of tabes in certain cases. But the facts recently brought by Fournier before the Académie de Médecine in reference to the relation between general paralysis and syphilis and its treatment are worthy of careful consideration and probation.

Fournier states that of 79 cases of general paralysis coming under his own observation in which he was able to obtain precise data as to the character and duration of the treatment to which they had been subjected, only 5 per cent. had been treated with thoroughness, while in at least 80 per cent. the antispecific treatment had been carried out in a more or less perfunctory manner. It is not enough, he says, to treat constitutional syphilis for weeks or months only. Fournier contends that mercurial treatment should be administered for at least two years continuously and intermittently for several years longer. "Treat syphilis well and you will have few cases of general paralysis," he says. The same would hold true of spinal tabes. These views deserve the special consideration of those who have most opportunities of treating syphilis in its earlier stages. If they are substantiated, tabes, both cerebral and spinal, will become one of the rarer instead of one of the most common and, it is to be feared, increasing forms of organic nervous disease

ON THE VALUE OF A SERUM (DOYEN'S) IN CASES OF MALIGNANT DISEASE.[1]

BY ALEXANDER PAINE, M.D., B.S. LOND.,
AND
DAVID J. MORGAN, M.A., M.D. CANTAB.,
CO-PATHOLOGISTS TO THE CANCER HOSPITAL, LONDON.

DURING the past year we have undertaken an inquiry at the Cancer Hospital into the treatment of cancer by means of Dr. Doyen's serum. The results of this treatment, together with an account of the pathological investigation of the occurrence of the so-called "micrococcus neoformans" in simple and malignant growths, form the basis of this paper. We think it advisable to preface our remarks with a brief *résumé* of Dr. Doyen's work on the subject. In 1886 Dr. Doyen sent a preliminary note to the Academy of Sciences at Paris recording his observations in malignant and other growths of small, spherical, mobile bodies which he regarded as micro-organisms. In 1901 he made a communication to the Academy of Medicine in Paris and in the following year to the surgical congress at Berlin corroborating these observations, and stating further that he had isolated a micro-organism from simple and malignant growths which when inoculated into animals gave rise to neoplastic formations, and this organism he named the "micrococcus neoformans." He also regarded all these growths as the result of an infection of the body with this organism, comparable to the infective processes of tuberculosis and actinomycosis. Early in 1904 he made a second communication to the Academy of Sciences in Paris announcing the preparation of anticancerous vaccines by attenuating and exalting the virulence of this organism. He had also by means of its toxins prepared an antitoxic serum from the horse. With these preventive and therapeutic remedies combined with surgical operation he had treated 126 cases of malignant and simple growths and of these 21 he regarded as cured. Since this date he has published in his book on the "*Étiologie et Traitement du Cancer*" an account of 116 additional cases, 42 of which he records as cured. During the year we were afforded every opportunity of watching the progress of cases so treated by Dr. Doyen at his clinique in Paris and were very kindly supplied by him with a quantity of vaccine and serum with which we have treated some nine cases of malignant disease. Most of these cases were seen by Dr. Doyen himself who regarded them as suitable for the treatment. The treatment consisted of the injection of 10 cubic centimetres of the serum or vaccine deep into the muscles of the buttock, with strict aseptic precautions, at stated intervals. We wish to state that as we were desirous of ascertaining the therapeutic value of these remedies all the cases were treated by them alone without surgical interference. We mention this because in many of Dr. Doyen's cases the two methods of treatment were combined.* The first part of the paper deals with a clinical account of the cases treated and the latter part with the results of the pathological investigation.

---

[1] A paper read before the Royal Medical and Chirurgical Society on March 27th, 1906

PART I.—CLINICAL INVESTIGATION.

CASE 1.—A man, aged 54 years, was admitted to hospital on March 17th, 1905, for recurrent epithelioma in the neck. In July, 1903, he had a growth (said to have been "cancer") removed from the centre of the back of the neck. In July, 1934, two recurrent nodules of growth appeared on either side of the back of the neck, close to the middle line and quite near to the spot wherefrom the growth was removed in July, 1903. The patient was advised to come up to the Cancer Hospital. This he did on Sept. 2nd, 1904. His general health was then good and he looked healthy. There was a healed scar in the middle line at the back of the neck. Above and on either side of this was a rounded raised ulcer with hard edges, the base being flat, with unhealthy granulations. There was a slight discharge from both ulcers. The ulcers were apparently fixed to underlying glands which were moveable on the deeper tissues. No other enlarged glands could be felt anywhere. The growth was removed on Sept. 20th and microscopically shown to be a definite epithelioma. Two subsequent local recurrences of the growth were removed in December of the same year and in January, 1905. On March 17th the patient was again admitted for a recurrent growth at the back of the neck which was painful and increasing in size. On examination, close to the right side of the occiput was a recurrent nodule of growth which was firm, hard, and red, adherent to the skin, which was not ulcerated, and deeper tissues. The growth was circular in shape and had a diameter of one inch. No glands could be felt anywhere. The patient was then given injections with Dr. Doyen's serum. During his stay in the hospital he received 15 injections from March 27th to May 8th. His general health remained good and he increased four pounds in weight. After the injections he experienced a feeling of increased tension in the growths which steadily increased to twice the size, when it was considered advisable to stop the injections.

CASE 2.—A man, aged 70 years, was admitted to hospital on March 23rd, 1905, for recurrent epithelioma in the lower jaw and glands (secondary to the lower lip). In July, 1903, the patient was operated on at St. Thomas's Hospital for "epithelioma of the lower lip," when the growth was removed. Since December, 1904, he had had a swelling under the left side of the lower jaw which had steadily increased in size. He complained of pain in the growth and earache. He had not lost flesh, his appetite was good, and he slept fairly well. There was slight dysphagia. The voice was normal. The patient was a big stout man whose general health was good. There was a slight scar on the left side of the lower lip, the result of previous operation. Occupying the whole of the left submaxillary and submental regions as far as the angle of the jaw and extending as low as the thyroid cartilage was a large, very hard mass of growth of the size of an orange, firmly fixed to the lower jaw and skin. There was no fluctuation or tenderness and the skin over the tumour was reddened. The right neck and jaw were apparently normal. Whilst in hospital he received 12 injections between March 27th and April 22nd, during which time his general health became much impaired and he gradually lost weight. The growth increased in size, softened, and broke down, leaving a cavity which discharged thin sanious fluid; and as this was followed by fever and general malaise the injections were discontinued. The disease ran its usual course and the patient died on June 2nd.

CASE 3.—A woman, aged 48 years, was admitted to hospital on March 31st, 1905, for carcinoma of the left breast. Two years previously she had a miscarriage. After this (in August, 1903) she noticed a small hard lump in the left breast which was not painful. In December, 1903, she went to the Samaritan Hospital where she was told that she had "cancer" of the breast. Nothing was apparently done then. In February, 1904, she went to the Middlesex Hospital. Operation was refused there owing to the fact that she suffered from bronchitis and emphysema and it was thought that she was not in a fit condition to withstand the anæsthetic. Since June, 1904, she had had x ray treatment at the Cancer Hospital. On admission the left breast contained a large hard mass of growth of the size of a Tangerine orange, which was not painful and which was adherent to the skin and to the pectoral muscle, though there was free lateral movement. The nipple was retracted and some enlarged glands could be felt in the left axilla but none in the supra clavicular fossa. The right breast and axilla were normal. There was no swelling of the arm. Examination of the chest showed that the patient was the subject of chronic bronchitis and emphysema. She received eight injections from March 31st to June 8th, during which time she lost two pounds in weight and suffered very much pain; this was so severe as to keep her from obtaining sleep. The pain was situated in the tumour, radiating to the shoulder and down the arm to the elbow and finger-joints. A localised erythematous rash appeared on the buttock after the third injection. At the patient's request the injections were discontinued and this was followed by a cessation of the pain. The tumour had increased in size. At a later date the breast was amputated by Mr. Charles Ryall and shown to be definite scirrhous carcinoma.

CASE 4.—A woman, aged 63 years, was admitted to hospital in April, 1904, for recurrent carcinoma of the left breast. In 1895 the late Sir William Banks operated on the patient for carcinoma of the left breast. Four years later (1899) this recurred and was allowed to remain for five years without treatment, when she came to the hospital in April, 1904. On admission there was a scar below the nipple of the left breast. The breast, nipple, and scar were all bound down in a large hard mass of growth, absolutely fixed to the skin and deeper parts. Just above and external to the nipple was a small ulcer with hard edges but with no granulations on the base. Some thickening was felt towards the axilla but no definite axillary glands. The veins over the left shoulder were dilated. No enlarged glands could be felt above the clavicle. X ray treatment was given while the patient was in hospital with no apparent result and she was discharged on June 10th, 1904. She was readmitted on Jan. 20th, 1905. Her general health was then poor. Examination at this time showed that in the scar of the amputation wound of the left breast was a small stony hard mass fixed to the chest wall. The surrounding skin was marked by radiating fissures. A mass of glands could now be felt in the axilla. The patient received five injections from March 29th to April 10th. Her general condition remained unimpaired until the last injection which was followed by severe constitutional disturbance characterised by depression, high fever, the temperature rising to 103·2° F., loss of appetite, dry brown tongue, and joint pains, an erythematous rash appearing over the lower part of the chest, abdomen, and both knees; heart failure and pulmonary congestion supervened, but under stimulants the cardiac condition improved and at the end of a week the temperature returned to normal, leaving the patient very feeble. She had lost eight pounds in weight. No change was observed in the local condition of the breast and the injections were discontinued.

CASE 5.—A man, aged 65 years, was admitted to hospital on April 12th, 1905, for epithelioma of the left tonsil with secondary glands in the left side of the neck. About three years ago (in 1902) a lump was first noticed on the left side of the neck. As the tumour grew larger and the patient had severe pains at the top of the head of a gripping nature he went to the Throat Hospital in the Gray's Inn-road in December, 1904, and was there told that nothing could be done. On the following day he went to St. Mary's Hospital and was there told that he had an inoperable cancer. He went to Dr. Doyen at Paris early in January, 1905, and was in his hospital for just over a month. During this time he had nine injections of serum, and he said that he felt much better, the pains in the head had disappeared, and he thought that the lump was smaller. He returned to London in the early part of February and came to the Cancer Hospital on April 12th, 1905, as the lump was then getting larger and the pains in the head had returned. On admission his general health was good. On the left side of the neck was a large egg-shaped tumour situated below the lobule of the ear. Its long diameter measured nearly four inches over the surface and commenced at a point one inch below the tip of the left mastoid process, extending downwards and forwards, following the course of the sterno-mastoid muscle. Anteriorly it reached to the angle of the jaw and extended backwards for a length of nearly three inches. The tumour itself was firm and hard, firmly incorporated with the left sterno-mastoid muscle, and fixed to the deeper structures of the neck. Its surface appeared lobulated, consisting of a larger upper mass and a smaller lower one; the skin over it was freely moveable and perfectly normal. This growth in the neck was continuous with an epitheliomatous mass on the left tonsil, the latter appearing as a growth with raised, hard, ragged edges, having an ulcerated surface and hard base. This extended downwards, laterally and slightly anteriorly to a point on a level with the middle of the epiglottis. The patient's voice was husky. He received 17 injections from April 14th to June 7th. During this time his general health remained fairly good, though he lost colour. The pain at the back of the neck, which radiated over the top of the head, gradually remitted and he expressed himself free from pain after the fourth injection. At the same time the lower end of the tumour in the neck appeared softer. After the eighth injection the pain returned with much severity and he suffered from depression. Immediately after the last injection the patient, in his own words, experienced "a feeling of suffocation and great difficulty in getting his breath; there was a feeling of swimming in the head as if the blood was rushing to the brain; he then became confused in his mind and felt as though he were dying." His face became suffused, his features swollen, and his eyes injected. The expression was one of anxiety. This was accompanied by dyspnœa, followed by cyanosis of the face (breathing being shallow, laboured, and quick). The pulse became very rapid and feeble and there was marked vaso-motor dilatation of the vessels of the skin all over the body and extremities, with general profuse sweating. Examination of the chest showed that the breath sounds were laboured and accompanied by a peculiar inspiratory stridor. This condition was followed by shivering, with coldness of the extremities. Cardiac stimulants were given and the collapse was treated in the usual way. After an hour the pulse, which had become almost imperceptible, gradually improved and the dyspnœa and cyanosis passed off, leaving the patient very weak. The skin remained injected and the features swollen for some hours. The patient slept well in the night and in the morning his temperature was subnormal. His pulse, which had reached 100 after the injection, had also become subnormal. There was absence of dyspnœa and the general injection of the skin had passed away, leaving the patient weaker. The injections were discontinued and though externally the growth did not appear to have increased very much in size an examination of the throat showed that the growth on the tonsil had extended downwards and forwards.

CASE 6.—A man, aged 61 years, was admitted to hospital on May 1st, 1905, for epithelioma of the left lower lip and cheek. Five years ago (1900) the skin of the lower lip on the left side became broken and sore (which the patient attributed to the irritation caused by smoking a clay pipe) A wart formed at this spot which was removed in July, 1902, at the London Hospital. A further operation was performed in the following October for recurrence. In September, 1904, he was again at the London Hospital when his teeth were removed but nothing was done to the growth. Since November, 1904, he had attended the Cancer Hospital as an out-patient. His condition on admission as an in-patient was as follows. On the left lower lip, occupying practically its whole length and spreading to the left angle of the mouth and the skin down to the lower border of the jaw and invading the margin of the gums to a little beyond the mid-line, was a ragged, raised, ulcerated mass of growth with hard edges. Its size was about two inches by two inches No enlarged glands could be felt. The patient's general health was good; he received 16 injections from May 2nd to June 19th, his general health improved, and he gained five pounds in weight, but as the growth steadily increased in size the injections were discontinued.

CASE 7.—A man, aged 58 years, was admitted to hospital on May 26th, 1905, for an epitheliomatous mass in the neck. In December, 1904, he first noticed a small lump behind and below the lobule of the right ear. It grew rapidly and was operated on by Mr. L. B. Rawling at St. Bartholomew's Hospital at the end of March, 1905. He remained there for three weeks and from the patient's account it is doubtful if the tumour was removed or not. The growth had continued to grow very rapidly. On admission there was a large oval-shaped tumour in the right side of the neck, extending from the lobule of the ear above to within two and a half inches of the clavicle. In front it reached the anterior margin of the sterno mastoid and posteriorly the anterior border of the trapezius. The surface was covered by thick, bluish, very congested skin and the upper part was traversed by a curved linear scar. There were three protuberances, over which the skin was very thin, and fluctuation could be felt. The whole mass was fixed to the deep structures. No growth was discovered in the mouth, tongue, or pharynx. No other tumours were found. There was no dysphagia and speech was not affected. The patient had pricking, throbbing pain in the growth, especially at night. There was no pain in the ear or in the temporal region. There was no deafness in the right ear. He received eight injections from May 30th to June 19th. Beyond a slight febrile reaction and an appearance of a local erythema on the buttock there was no change noted in the patient's condition until immediately after the last injection was given, when he experienced sensations similar to those recorded in Case 5. The onset of the attack commenced with a feeling of suffocation, accompanied by a rush of blood to the head and followed by temporary loss of consciousness. He also felt pain in the back. There were temporary cessation of breathing, suffusion of the face which became very red, injection of the conjunctivæ, and swelling of the features. The lips and hands became cyanosed and the body and extremities cold. When respiration again commenced it was laboured, the breath sounds over the sides of the chest being peculiar; expiration was prolonged and followed by stridulous inspiration, with an occasional loud rhonchus. The pulse at this period was faint, fairly regular, and of medium tension—88 per minute. After a few minutes the pulse rose to 120, and this was followed by a rigor, the lips remaining cyanosed and the features swollen. There was profuse sweating of the face but not of the body. The feet became somewhat œdematous. The collapse was treated in the usual way. During this period the temperature in the axilla rose to 104° F.; subsequently it fell to below 97°. The patient slept in the night and next day expressed himself as feeling much better, but the eyes, the cheeks, and the lips were œdematous and pale, and there was slight œdema of the feet. The respiration and pulse were normal. The urine passed in the night was examined, but nothing abnormal was found. After June 19th, 1905, no further injections were given. The growth subsequently ulcerated through in several places, leaving sinuses with large fungating orifices. The patient died on August 27th, 1905.

CASE 8 —A woman, aged 55 years, was admitted to hospital on May 22nd, 1905, for carcinoma of the left breast. Two years ago she first noticed a moveable lump near the left axilla. This gradually became bigger and for the last year the breast had progressively increased in size. The whole breast seemed to increase uniformly and she had never noticed any tumour in the breast substance. The skin over the breast had become blue for the last three months. On admission the whole of the left breast was uniformly enlarged by a hard firm tumour, the whole organ being unduly prominent and firmly fixed to the deeper structures. The skin over it was of a bluish colour and fixed in all parts over the breast; it was infiltrated everywhere over the tumour with growth and was very much thickened. The nipple was slightly retracted. Enlarged glands were felt in the anterior border of the left side and in the left axilla. She received four injections from June 5th to 13th. After the second injection the pain in the breast became very severe and increased in severity after the third. After this injection a local erythema appeared on the buttock, the skin over which became very brawny. After the fourth injection the pain in the breast became intense and extended to the shoulder and down the arm. The latter was much swollen and covered on its extensor surface with an acute erythema. After this date no further injections were given in the hospital.

CASE 9 —A woman aged 52 years, was admitted to hospital on May 27th, 1905, for carcinoma of the cervix uteri. The history on admission was as follows. The patient was a married woman and had had eight children, the last 15 years ago. Menstruation ceased 10 years ago. She first noticed pain—sharp and smarting in character—in January, 1905. This was constantly present and had become more severe lately. There was no aching in the back. A vaginal discharge was noticed two months ago, becoming blood-stained one month ago. The discharge was not foul. There had been no increased frequency of micturition and the bowels were normal. She had been losing weight recently. Abdominal examination was negative. No iliac glands were palpable. Per vaginam the left side of the cervix uteri was found to be occupied by a hard, friable mass which readily bled on touching and involved about two-thirds of the circumference of the external os uteri. The whole uterus was slightly fixed on the left side. This patient had six injections but beyond the appearance of local erythema at the site of inoculation after the third injection there was little to record in this case, for she refused further treatment, complaining of pain and insomnia which she attributed to the injections.

Comment on the cases.—The cases treated will be considered under the following headings: (1) those in which the injections had no influence on the course of the disease; (2) those in which the injections were followed by severe pain; and (3) those in which the injections were followed by severe constitutional disturbance.

1. *Those in which the injections had no influence on the course of the disease.*—These were four in number. One of the cases—Case 2—has since died. A second—Case 1—has undergone three subsequent operations for removal of recurrences of the growth in the neck. A third—Case 6—is now attending the hospital as an out-patient. A fourth—Case 9—refused to continue the treatment.

2. *Those in which the injections were followed by severe pain.*—These were cases in which the patients were suffering from carcinoma of the breast—viz., Case 3 and Case 8. In the former case the pain which was extremely severe was located around the growth, radiating from the breast to the back, shoulders, and down the arms. Sleep had often to be procured by morphine. The pain finally became so severe that the patient refused to continue the injections. In the latter case the pain was very severe in the breast and down the arm.

3. *Those in which the injections were followed by severe constitutional disturbances.*—These cases were characterised by cardiac failure. In one—Case 4—this developed gradually and was accompanied by high fever, depression, pain, and other symptoms of constitutional disturbance. In the others—Case 5 and Case 7—the onset was sudden, occurring immediately after the injection, and was accompanied by widespread vaso-motor disturbance and collapse. In Case 4 the symptoms were those of a profound toxæmia—viz., continuous high temperature, headache, dry furred tongue with loss of appetite, general aching pains throughout the body and especially in the joints, a morbilliform rash on the trunk and local œdema over the joints, anæmia, feeble circulation, and great prostration. When the injections were withheld she made a slow and imperfect recovery so far as her general health was concerned. This severe reaction was not accompanied by any amelioration of the condition of the breast or improvement in the general health. Two or three weeks after the last injection she developed pain down the spine and subsequently paraplegia. In this connexion it is interesting to record that Mr. Ryall had under his care at that time two cases of carcinoma of the breast complicated by paraplegia, and these have not been treated with serum. We mention this because it might be wrongfully inferred that this paralytic condition was due directly to the injection. In the other two cases—Case 5 and Case 7—the failure of the heart's action came on suddenly and was accompanied by severe dyspnœa which first suggested pulmonary embolism but examination of the chest did not confirm this. The immediate onset and widespread distribution of the symptoms may have been due to some obscure reflex action or might be explained by assuming that possibly the injection had been made into a vessel—i.e., directly into the circulation. If the latter were the case, the symptoms might be explained by the serum in Case 5 and the vaccine in Case 7 acting either directly on the central nervous system or by producing active congestion of the tumour, causing direct pressure on the great vessels and nerves of the neck, for both these patients were suffering from large tumours in the neck surrounding the large vessels and nerves. In Case 7, who has since died, at the *post-mortem* examination it was found that these structures were closely incorporated in the growth at the level of the bifurcation of the common carotid. The symptoms in the two cases were not exactly the same; they resembled one another in the sudden onset of the cardiac failure, but differed in the extent and distribution of the vaso-motor disturbance, being general in Case 5 but localised to the head and neck in Case 7. This may be explained by the fact that a serum was used in the former case and a vaccine in the latter, or by the difference in the anatomical relations of the two growths. A number of rabbits were injected intravenously at the Brown Institution with both the serum and vaccine, but although large doses were given no ill-effects were produced; but the possibility of a difference in susceptibility to toxins between man and animals has to be borne in mind. Owing to the severe constitutional disturbances which followed the last injections in the three cases above mentioned, coupled with the fact that in none of the cases treated by injections was there any improvement, it was decided to suspend the treatment.

PART II.—PATHOLOGICAL INVESTIGATION.

The lines upon which this investigation has been conducted are those which Dr. Doyen has set forth in his book on the "Étiologie et Traitement du Cancer." We have used his methods of technique and supplemented them by others of our own. It may here be stated that the principles of the methods adopted by Dr. Doyen are those in general use in pathological research and differ from them only in a few minor details of technique. The cases selected for examination were all characteristic examples of simple and malignant growths, diagnosed clinically as such by the surgeons of the hospital, the diagnosis being confirmed by subsequent microscopical examination. A large number of the cases selected for investigation were mammary growths, both primary and recurrent, together with their secondary deposits in the symphatic nodes. We chose these tumours for preference, regarding them as being less liable to infection with laprophytic organisms than those connected with mucous membranes, where the moist surface favours the excoriation of epithelium and hence the invasion of bacteria. We have examined the acute and rapidly growing tumours as well as the more chronic and slower growing varieties and in every case the examination of the tumour was carried out immediately after its removal from the body. In all we have investigated 44 cases.

The microscopical examination of a very large number of simple and malignant tumours in films and sections prepared from the growth has shown us that the presence of micro-organisms in these pathological structures is by no means constant. In a large number of growths we have failed to demonstrate the presence of any organisms. In cases in which we have succeeded in detecting them the micro-organisms have been of various kinds and were members of the coccal and bacillary groups of bacteria. No one particular organism has been found to be constantly present. In those cases in which we have failed to demonstrate the presence of any micro-organism in films or sections cultures taken from the same growths have generally proved to be sterile. Our attention has been specially directed to the study of those tumours in which the members of the coccal group were present. We have endeavoured to ascertain (1) the nature of the organism when present; (2) the extent to which it was present; and (3) the relationship of the organism to the special cellular elements of the growth.

1. Micrococci when present in the tumours appeared in the form of solitary cocci and diplococci, and as these are the morphological appearances which micrococci assume in tissues when not in the state of active growth it was consequently impossible to identify them by this method of examination with any one particular species of micrococcus.

2. We also found that the organisms were present in very small numbers and we did not find them in greater numbers in the more rapidly growing tumours than in the slower-growing varieties.

3. Owing to the small number of organisms present in such tumours and the consequent difficulty of detecting them microscopically we have reinforced their numbers by the method of incubating the tissues at the body temperature. We did not find that the micrococci bore any special relation to the cells of the growth. Sometimes they were intracellular but more often extracellular.

Cultivations were made from each of the 44 tumours from different cases investigated and the manner in which this was done was the same as that usually adopted in taking cultures from any solid organ. The surface of the tumour, which had been removed at the operation, was seared with a cautery and with sterile knife and forceps, portions were removed from the growing edge and also from the centre of the growth and immediately immersed in liquid media with the strictest aseptic precautions. The cultures thus made were incubated at the body temperature for a period of from one to seven days. These were examined daily and films made from them, stained, and submitted to microscopical examination. The liquid media we have used include one specially advocated by Dr. Doyen for the isolation of his organism—namely, "*bouillon de mamelle de vache.*" This is a watery extract of the cow's udder in lactation, to which peptone and salt are added, and the whole rendered sterile by heat in the autoclave at 130° C. We also used ordinary peptone-bouillon and similar media, to which glycerine (4 per cent.) and glucose (2 per cent.) have been added in the usual way. Sub-cultures from the liquid media were made on solid media, such as agar-agar, gelatin, and potato, in order to study the characters of the growth of the organism on various media; and also for subsequent use for experimental purposes of inoculation. (*Vide* Table II.)

TABLE I.—SUMMARY OF THE CASES.

No.	Age in years.	Disease.	Condition.	Number of injections.	Constitutional reaction.	Local change in growth.	General health.	Remarks.
1	54 (male).	Recurrent epithelioma of the neck.	Operable.	15	*Nil.*	Increase.	Unimpaired.	General health remained very good. Gained four pounds in weight whilst under treatment. Increased tension in growth followed the injections.
2	70 (male).	Epithelioma of the lower jaw secondary to the lower lip.	Inoperable.	12	*Nil.*	"	Impaired.	No relief of pain. The disease ran its usual course; death.
3	48 (female).	Scirrhus of the left breast.	Operable.	8	Marked increase of pain.	"	"	Lost two pounds in weight. Local erythematous rash over the site of the inoculation. Marked increase of pain in the breast. General aching pains in the joints.
4	63 (female).	Atrophic scirrhus of the left breast.	"	5	Cardiac failure.	*Nil.*	"	Severe constitutional disturbance accompanied by a morbilliform rash on the front of the body, high fever, general aching pains in the joints and all over the body, together with cardiac failure followed the last injection.
5	65 (male).	Epithelioma of the left tonsil.	Inoperable.	17	Cardiac failure and collapse.	Increase.	"	Temporary relief of pains in the head. Severe constitutional disturbance followed immediately on the last injection, characterised by cardiac failure and vaso-motor disturbance.
6	61 (male).	Recurrent epithelioma of the lower lip.	"	16	*Nil.*	"	Unimpaired.	General health remained very good. Gained five pounds in weight during stay in hospital.
7	58 (male).	Epithelioma of the neck.	"	8	Cardiac failure and collapse.	"	Impaired.	Temporary relief of pains in the growth and freer lateral movement of the head. Severe constitutional disturbance followed immediately on the last injection, characterised by cardiac failure and vaso-motor disturbance.
8	55 (female).	Carcinoma of the left breast.	"	4	Marked increase of pain.	"	Unimpaired.	Local pain and tenderness in the buttock with injection and brawny swelling of the skin over the site of inoculation. Increased pain in the breast and erythematous rash on the arms.
9	52 (female).	Epithelioma of the cervix uteri.	"	6	*Nil*	*Nil.*	"	The patient refused to continue the treatment, complaining of pain and insomnia which she attributed to the injections.

In this manner we have examined 44 cases—viz., epitheliomata, 7; carcinoma of the breast, 25; sarcomata, 3; lymphadenoma, 2; fibro-adenoma, 2; myxoma, 1; lipoma, 1; and inflammatory tumours, 3. The organism named by Dr. Doyen the "micrococcus neoformans" was present in 11 of the 44 cases—i.e., in 25 per cent. of all the cases examined; the "micrococcus neoformans" was present in one of the seven cases of epithelioma, in seven of the 25 cases of carcinoma of the breast, in two of the three cases of sarcoma, in the case of myxoma, but in none of the eight cases of other tumours. Of these 11 cases in which the "micrococcus neoformans" was present it appeared in pure culture in eight cases and in the remaining three it was present with other organisms. In cultures which are sterile Dr. Doyen states that the "micrococcus neoformans" can be demonstrated in the sediment at the bottom of the liquid cultures. Of the 16 of our cases which gave sterile cultures the sediment at the bottom of the tubes was carefully examined, but in no single instance were we able to identify an organism with the "micrococcus neoformans." Of other organisms which were found to be present in the tumours we examined we draw attention to the fact that a streptococcus was found in 13 out of the 44 cases, as compared with 11 in which the "micrococcus neoformans" was present.

A study of the "micrococcus neoformans" shows that it is a polymorphic coccus measuring from less than 0·5 to rather more than 1μ in diameter. It possesses an outer envelope which does not stain easily but has no definite capsule. It is usually associated in pairs and when growing in liquid media appears in short chains. Occasionally one of the elements dividing in a direction parallel to the long axis produces a bifurcation of the chain. The organism stains well with the ordinary aniline dyes and is not decolourised by Gram's method. It grows readily on ordinary media. On agar-agar it forms a raised, white, moist, shiny and viscid growth which can be easily detached from the medium. On gelatin the growth is similar and is accompanied by slow liquefaction of the medium; and as the organism is preferably an aerobe stab cultures in gelatin are characterised by cupping of the superficial portion of the stab. In bouillon the growth appears as a general cloudiness of the medium which gradually clarifies by sedimentation of the growth to the sides and bottom of the tube.

With a view to ascertaining the pathogenic action of the "micrococcus neoformans" on animals a series of experiments have been conducted at the Brown Institution. The animals used were rats and mice. The method of inoculation was intraperitoneal, as used by Dr. Doyen in his researches. In all 200 animals were inoculated—viz., 110 mice and 90 rats. The organisms used in these cases were obtained from four different tumours—viz., carcinoma of the breast, carcinoma of the neck, carcinoma of the ovary, and melanotic sarcoma. The organism in the two latter cases had been isolated by Dr. Doyen who very kindly supplied us with subcultures. Many of these animals died from natural causes, others as the result of the inoculation, and of those which survived half the number were killed at the end of three months and the remaining half at the end of six months. In none of the animals did we find any evidence of simple or malignant tumours as a result of inoculation. In the animals which died from natural causes we found large tapeworm cysts in the liver and in a few cases pneumonia. In those animals which died as a result of the inoculation the cause of death was found to be either peritonitis or broncho-pneumonia. In the animals which survived and were killed at three and six months nothing abnormal

TABLE II.—TABULATED SUMMARY OF THE CASES.

No.	Nature of tumour.	Ulcerated or not.	History.	Organisms present.	Presence or absence of the "micrococcus neoformans."
*1	Recurrent epithelioma of the neck.	Yes.	3 months.	Polymorphic micrococcus.	Present.
2	Epithelioma of the neck, secondary to the tongue.	Yes.	12 ,,	Solitary micrococci; streptococci; diplococci; short bacilli.	Absent.
3	Epithelioma of the tongue.	Yes.	12 ,,	Streptococci.	,,
4	Fibro-adenoma of the breast.	No.	3–4 years.	Streptococcus longus.	,,
5	Carcinoma of the breast and axillary glands.	No.	6 weeks.	None.	,,
6	Sarcoma of the breast and axillary glands.	No.	4 months.	Polymorphic micrococcus obtained from the axillary gland.	Present.
7	Mastitis.	No.	—	None.	Absent.
8	Epithelioma of the jaw (recurrent) secondary to the lip.	No.	3 months.	,,	,,
9	Recurrent carcinoma of the axillary glands, secondary to the breast.	No.	4 ,,	Streptococci.	,,
10	Carcinoma of the breast.	Yes.	2 years.	,,	,,
11	Myxoma of the parotid.	No.	—	Polymorphic micrococcus.	Present.
12	Epithelioma of the lip.	Yes.	4 months.	Streptococci.	Absent.
13	Carcinoma of the left breast.	No.	—	None.	,,
14	Carcinoma of the right breast and axillary glands.	No.	7 weeks.	,,	,,
*15	Recurrent epithelioma of the neck.	No.	3 months.	Polymorphic micrococci; short bacilli.	Present.
16	Epithelioma of the lip.	No.	3 ,,	Micrococci.	Absent.
17	Recurrent carcinoma of the breast and axillary glands.	No.	4 ,,	Polymorphic micrococci; streptococci in growth; polymorphic micrococci in gland.	Present.
18	Recurrent carcinoma of the breast.	No.	4 ,,	Polymorphic micrococcus.	,,
19	Paget's disease of the right breast.	Yes.	4 years.	None.	Absent.
20	Carcinoma of the breast.	No.	9 months.	Polymorphic micrococcus.	Present.
21	Recurrent carcinoma of the axillary glands, secondary to the breast.	No.	2 years.	None.	Absent.
22	Lymphadenoma of the left neck.	No.	—	Streptococci.	,,
†23	Carcinoma of the breast.	No.	4 months.	None.	,,
24	,, ,,	Yes.	12 ,,	,,	,,
25	,, ,,	No.	2 years.	,,	,,
‡26	Sarcoma of the breast.	No.	1 month.	Micrococci; small bacilli.	,,
†27	Recurrent carcinoma of the supraclavicular glands, secondary to the breast.	No.	4 months.	Staphylococcus; polymorphic cocci; small bacilli.	Present.
*28	Recurrent epithelioma of the neck.	No.	4 ,,	Polymorphic cocci; small bacilli.	,,
29	Melanotic sarcoma of the breast, axillary glands, and abdominal wall.	No.	1 year, 7 months, and 6 months respectively.	Breast: Polymorphic bacilli. Glands: Polymorphic micrococci. Abdominal wall: Large and small micrococci.	Present (only axillary glands).
30	Granuloma of the liver.	No.	18 months.	None.	Absent.
31	Carcinoma of the breast and axillary glands.	No.	19 ,,	Polymorphic bacilli; polymorphic micrococci; staphylococci.	Present (in grow only.)
32	Fungating carcinoma of the breast, enlarged glands, axilla, &c.	Yes.	12 ,,	Streptococci; bacilli.	Absent.
‡33	Sarcoma of the breast (recurrent) and axillary glands.	No.	3 weeks.	Streptococci; bacilli (in growth).	,,
34	Carcinoma of the breast.	No.	2 ,,	Micrococci; small bacilli.	,,
35	Carcinoma of the breast and axillary glands.	No.	—	None.	,,
36	Carcinoma of the breast.	No.	2 weeks.	,,	,,
37	Lymphadenoma of the left neck.	No.	18 months.	Streptococci.	,,
38	Recurrent epithelioma of the glands in the groin, secondary to the foot.	No.	1 month.	Streptococci.	,,
39	Chronic adenitis of the inguinal glands.	No.	8 months.	None.	,,
40	Carcinoma of the breast and axillary glands.	No.	2 years.	Streptococci *in gland only.*	,,
41	Carcinoma of the breast (in lactation) and axillary glands.	No.	2 months.	Diplococci in growth resembling the pneumococcus.	,,
42	Carcinoma of the breast and axillary glands.	No.	2 years.	None.	,,
43	Carcinoma of the breast and axillary glands.	No.	1 month.	Polymorphic cocci in growth and gland.	Present.
44	Fibro-adenoma of the breast.	No.	10 months.	Small bacilli.	Absent.
45	Recurrent carcinoma of the infraclavicular glands, secondary to the breast.	No.	11 ,,	None.	,,
46	Carcinoma of the breast and axillary glands.	No.	5 ,,	Bacilli (in growth); polymorphic cocci (in gland).	Present (in glan only).
*47	Recurrent epithelioma of the neck.	No.	4 ,,	None.	Absent.
48	Carcinoma of the breast and axillary glands.	No.	2 ,,	Micrococci (in growth); bacilli (in gland).	,,
49	Lipoma of the axilla.	No.	3 years.	None.	,,

* Removed from the same patient at different times of recurrence. (See Case 1, Clinical Investigation.) † Removed from the same patient at different times of recurrence. ‡ Removed from the same patient at different times of recurrence.

was found beyond worm cyst in the liver in a small percentage.

It will thus be seen that the experimental results we have obtained by the inoculation of the "micrococcus neoformans" into rats and mice have in every case been of the inflammatory character analogous to those we should expect to result from the inoculation of these animals with organisms of the same class. In no single instance have we met with tumours, either simple or malignant, in the animals we have inoculated. Most of the microscopical preparations obtained from Dr. Doyen's own animal experiments, and which we had the privilege of examining in his laboratory during our visits to his clinique at Paris, appeared to us to be of an inflammatory nature. Some of them, however, bore microscopically a superficial resemblance to carcinomatous and sarcomatous formations and these were localised and very small, and were unaccompanied by secondary deposits in the lymphatic nodes or generalisation in the organs; nor were they accompanied by wasting or the other clinical attributes of malignant disease. The animals were killed by him at fixed intervals of three, six, and nine months. A few of the microscopical preparations resembled in their structure simple growths, such as adenoma, lipoma, and chondroma. It is known that rats and mice, in common with the rest of the animal kingdom, are liable to tumour formations. That mice are subject to cancer, analogous to cancer in man, and that *it may arise spontaneously* is now an established fact.

In no single instance has Dr. Doyen to our knowledge produced cancer in mice or rats. The fact that malignant growths can arise spontaneously in these animals makes it highly probable that simple growths might have a similar origin. If such is the case those tumours which Dr. Doyen has met with in the large number of mice and rats he has inoculated may have existed prior to the inoculation. He himself, however, attributes their formation to the action of the "microcococcus neoformans," with which the animals were inoculated, in that he found the organism present in the growths at the time he killed the animals some months after inoculation. It is well known that micrococci can exist for long periods in the tissues of the body as parasites; and if an animal possessing a tumour were inoculated with such an organism we think it is highly probable that it would settle in the growth, for in man a large variety of bacteria are often found to be present in tumours and appear in cultures taken from such growths, whilst they are absent in the neighbouring healthy tissues.

The presence of organisms in tumours admits of two explanations—firstly, in tumours arising from the deeper layers of the epithelium in the skin and mucous membranes, where organisms are constantly present, it is quite conceivable that the bacteria grow *pari passu* with the tumour and accompany it throughout its life-history, being carried in the secondary deposits to the lymphatic glands and to the metastases. A polymorpho-coccus differing from the micrococcus neoformans only in its manner of growth on gelatin and potato is found in the skin, and Dr. Doyen himself has discovered the "micrococcus neoformans" in the secretion of a breast which was not the seat of a tumour. Secondly, in those tumours which do not arise in connexion with the skin and mucous membranes it is probable that the organisms reach them through the lymphatics—in this connexion the occurrence of a streptococcus in pure culture in two of our cases of lymphadenoma of the neck is interesting when we consider how prevalent this class of organism is in the mucous membrane of the throat. The streptococcus obtained from these two cases, inoculated beneath the skin of rabbits, was not followed by any neoplastic changes in the nearest lymphatic glands.

In conclusion, we would say that the organism which Dr. Doyen has named the "micrococcus neoformans" is, in common with other micrococci, often present in malignant tumours; but in our opinion it is not present in sufficient numbers, or with reasonable constancy, to be regarded as the etiological factor in the evolution of these growths. Moreover, in our hands the inoculation of animals with this organism is not followed by the formation of neoplasms but by the expression of an inflammatory reaction.

HOSPITAL SUNDAY FUND AT BRISTOL.—At a meeting of the committee of this fund held on March 29th it was stated that £2076 had been received this year against £2053 in 1905. The following grants were made: Royal Infirmary, £811; General Hospital, £680; Children's Hospital, £257; Eye Hospital, £121; and £120 were distributed among the dispensaries and smaller hospitals.

A NOTE ON

THE PATHOLOGY OF GANGRENE AND PERFORATION OF THE HOLLOW ABDOMINAL VISCERA AND "ACUTE PERFORATING ULCER OF THE STOMACH."

BY DAVID DRUMMOND, M.D., D.C.L.,
SENIOR PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE;
AND
RUTHERFORD MORISON, F.R.C.S. ENG.,
SENIOR SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

CERTAIN of the hollow viscera—viz., the gall-bladder, the vermiform appendix, the cæcum, the urinary bladder, and the stomach—are subject to gangrene followed by perforation as the result of acute intra-visceral tension. In all, the condition is likely to be complicated by the intrusion of micro-organisms, but we suggest that mechanical causes are the chief factors in its causation. The striking similarity of the pathological appearances met with in all these viscera suggests a probable similarity in their origin. It seems to us extraordinary that this should have escaped notice, but, so far as we can find, little has been done to show how the behaviour of one of them under certain stimuli may be a guide to the conduct of the others in similar circumstances.

Our present paper only concerns patchy gangrene followed by perforation; this follows certain laws and is to be found affecting all the viscera that we have named. In all the forms of gangrene which we are considering the lesion commences as a small patch more or less circular in outline and at that portion of the wall of the viscus farthest from the source of its vascular supply.

The gall-bladder.—In the gall-bladder perforation generally occurs through a gangrenous patch at the fundus and is due to a stone impacted in and blocking its neck or the cystic duct, thus causing retention and consequent infection of the contents. Yet the perforation is not due purely to mechanical causes, for mechanical distension of the gall-bladder sufficient to produce rupture causes a leak near the neck of it, not near the fundus. The gangrenous patch at the fundus is roughly circular in shape and occurs at the position farthest removed from the origin of the cystic artery.

The vermiform appendix.—In the vermiform appendix, acutely inflamed and distended, gangrene first appears as a patch towards the tip and opposite its mesentery—that is, farthest from the origin of the branch of the ileocolic artery which supplies it. It is of some interest to note that in a single case of acute appendicitis, in which one of us (R. M.) excised the appendix only five hours after the commencement of the attack, there is shown a small patch in the position named of the lining mucous membrane which already exhibited signs of gangrene.

The cæcum.—More than once in opening the abdomen for intestinal obstruction due to stricture of the colon we have seen a gangrenous patch or patches circular in shape on the distended tense cæcum. These occur on its anterior surface in the neighbourhood of the anterior longitudinal band, that is, in the position farthest from the source of its vascular supply.

The urinary bladder.—For the urinary bladder the same rule appears to hold good. A man, aged 25 years, was admitted to the Royal Infirmary under the care of one of us (R. M.) suffering from retention of urine of four days' duration due to gonorrhœal prostatic abscess and excessive whisky drinking. His peritoneal cavity was distended with urine which had escaped through "a small round opening scarcely so large as a split pea, of grey ashy colour, at the superior portion of the posterior wall of the bladder"—i.e., the portion farthest from the main supplying vascular trunks.

The stomach.—Certain so-called ulcers of the stomach, we suggest, have a similar causation; the reasons on which this observation are based require some consideration. It is recognised by all authorities that there are two distinct types of "ulcer" of the stomach—(1) acute, and (2) chronic, and that the pathological causes of both are still undetermined. The chronic ulcer, with long history of previous gastric trouble, usually situated about the lesser curvature, of irregular shape, and with hard edges, does not concern our present remarks. The so-called acute ulcer, which is comparatively rare, is of great interest in the present connexion. It is situated on a line drawn along the stomach from the centre of the cardiac to the centre of the pyloric orifice—i.e., farthest from the main vessels of supply. Unlike the chronic ulcer it is strikingly circular in shape. Its edges are not infiltrated or hard and examination of recently perforated specimens shows that the edges of the perforation are composed of gangrenous tissue. A frequent history noted by all observers is that serious stomach symptoms have not, as a rule, preceded the attack. Another point frequently observed, and which our view only, we think, explains, is that a second ulcer may be found on the posterior wall at a spot opposite that on the anterior.

We are indebted to Dr. J. Collingwood Stewart, late resident house physician at the Royal Infirmary, for an answer to certain questions which we considered might be usefully inquired into in the history of cases of gastric ulcer. The first was as to symptoms which might be caused by attacks of acute distension of the stomach. He ascertained that, with few exceptions, patients in whom a diagnosis of gastric ulcer had been made were subject to attacks of *epigastric pain with a feeling of distension, accompanied by* breathlessness, sufficient to necessitate loosening corsets or tight bands. In all cases where the diagnosis was verified by operation these symptoms were present.

We thought that excess of hydrochloric acid in the stomach might be accounted for by an extra consumption of sodium chloride and the second question referred to the liking for salt. Dr. Stewart's inquiry showed that out of 40 chlorotic girls more than one-half (25) took an unusual quantity of salt. Of 30 patients with symptoms of gastric ulcer three-fifths liked salt in excess. One "carried a piece constantly"; another "took a pinch whenever she got a chance."

Our view briefly is that excess of hydrochloric acid in the stomach, by producing pyloric spasm and acute gastric distension in an anæmic girl, gives rise to a small gangrenous patch or patches in the stomach wall, and that subsequent digestion of the dead or devitalised patch, if all the coats are involved, leads to perforation. It is generally recognised that the stomach juices in certain circumstances destroy its own wall. We may add that a sudden attack of distension due to pyloric spasm in the case of a chronic ulcer probably accounts for perforation in many instances.

Newcastle-upon-Tyne.

THE RESULTS OF OPERATION FOR RADICAL CURE OF HERNIA.[1]

BY J. HUTCHINSON, JUN., F.R.C.S. ENG.,

SURGEON TO THE LONDON HOSPITAL.

THE aim of this paper is to test in the most stringent manner possible the results of an operation—that for radical cure of hernia—which now occupies a large proportion of the surgeon's time and energy. I find, for example, that over 500 out of a total of 4500 operations which I have performed in the London Hospital during the last 15 years have been done on herniæ. Thus it is probable that at least one-tenth of the general run of surgical operations in our hospital work is directed to obtaining the radical cure of hernia. The proportion of the different forms may be roughly estimated from my own record: inguinal hernia, 360; femoral hernia, 100; and umbilical, ventral, &c., herniæ, 50. These include about 150 cases of strangulated hernia. The answer to the question,—In what proportion is a permanent and complete cure obtained?—has been a varied one. As Mr. John Langton wrote in 1899[2]: "Afterwards ...... is after all the crucial test of our operative work; at present this 'afterwards' too often lies buried in the depths of the great unknown from causes over which we have but little control." Mr. Langton limited his consideration to cases of inguinal hernia in private practice and concluded, without giving exact statistics, that "in properly selected cases cures will result temporarily, at any rate, in about 80 per cent., but it is probable that relapses are not infrequent."

I would urge that hospital patients afford a better test of the operation for radical cure than do private ones, granting that it is more difficult to follow up those belonging to the former class. It is in those who are engaged in hard manual labour—in stokers, soldiers, railway porters, and the like—that the result of our procedure is best estimated. Moreover, certain conditions must be thoroughly applied, especially with regard to the length of time that has elapsed since the operation. Bassini, to whom surgeons are indebted for having shown the importance of opening up the inguinal canal in the great majority of cases, reported cures in no less than 96 per cent. But his limit of time—nine months or over—was certainly too short and to some extent invalidates his statistics. I have taken as the shortest limit two years from the operation, but so many of my cases have been examined seven, eight, or even ten years afterwards that the average works out at about six years. This will probably be accepted as sufficient. If a man has engaged in his ordinary work for six years after the operation and shows not the smallest sign of recurrence the term "radical cure" may fairly be applied. Again, differing from some authorities, I reject the use of any truss after the operation, since the *patient has submitted to it*, as a rule, in order to dispense with the inconvenience of wearing one. In four or five of the cases included in my list the patient has of his own choice worn a truss at some time or other after the operation but not on account of recurrence. In all cases of umbilical hernia after operation an abdominal belt should be worn; in a few examples of inguinal hernia (especially the direct form) and of femoral hernia in elderly people a truss is ordered after the operation. But in the statistics that follow it will be understood that these conditions have been carefully observed: (1) that at least two years, and on an average from five to six years, have elapsed before the result is tested; (2) that no truss has been ordered to prevent recurrence and that within six weeks of the operation (often less) the patient has been directed to return to his work; (3) that the smallest tendency to bulge at the site of operation has been considered as a recurrence of the hernia; and (4) that any development of a hernia at another site has been recorded. The last point will be found to be of considerable importance, though it is curiously omitted by nearly all the writers on the subject.

The result of operation for radical cure on inguinal hernia.—Formerly it was considered inadvisable to operate on hernial subjects (apart from strangulation) who were over 40 years of age. But of late years this limit has been extended and in my list six patients were 50 years old or over. The best results of all are certainly to be obtained on young children, but it happens that only four of the cases in my list were under the age of five years at the time of operation. The great majority were men between 20 and 40 years of age. I have followed up 109 patients after operation on inguinal hernia with the limit of at least two years. In four of these the herniæ were double, making a total of 113. 13 were cases of strangulation (with five recurrences) and it seems fair to leave these out since several were patients of very advanced age, three being 55 years old, one 65 years, and one 74 years. Out of 100 cases primarily done for radical cure, eight of the herniæ have relapsed *in situ*; of these in five the recurrence was pronounced, one very slight, and two doubtful. Seven patients have since the operation developed an inguinal hernia on the opposite side and one a femoral hernia. I must admit that this result, 8 per cent. or less of true recurrence, is somewhat better than I had expected.

After all, the formation of a hernia elsewhere does not detract from the original operation being termed a radical cure. And if, judged from the most severe standpoint, the proportion of relapses is only from 6 to 10 per cent., the use of the words "radical cure" is thoroughly justified. The statistics of several surgeons relating to Bassini's method practically agree with my own. Thus Carlé and Nicoladoni found 6 per cent. of relapses *in situ*, and Ceccopieri and Scarrone 7 per cent. One may be allowed some suspicion of the much more favourable results that are now and then brought forward. Thus Lucas-Championnière claims to have had only 4 per cent. of recurrence but in one of his tables it will be noticed that only half the total number were followed up for more than two months! This fact, to my mind, renders valueless his statistics, since recurrence, if it does follow, usually occurs from nine to 18 months after the operation. There is, of course, no infallible limit and of the eight cases of recurrence in my list one developed two years and two others three years after the operation; until that time had elapsed the cure appeared to be perfect. Some of my cases were operated on 15 years ago and there is no doubt that improved methods during this time have diminished the proportion of recurrence. Mr. Langton quotes Tilanus's statistics in 1879 of only 10 per cent. of cures and Socin's of only 40 per cent. It is, however, surprising to find Bull, in a fairly recent paper, stating that 60 per cent. of his cases ultimately relapsed. There must surely have been some grave fault in the form of operation.

---

[1] A paper read before the Medical Society of London on March 28th, 1906.

[2] Transactions of the Medical Society of London, 1899, p. 204.

Before considering the question of the relative value of the different methods now employed I may allude to one satisfactory fact that came out in the investigation of the cured cases. Practically without exception these patients stated that their operation scars never gave them the slightest trouble and many expressed themselves as improved in general condition and vigour by the removal of the hernial protrusion.

The best methods of radical cure.—I believe that on only two points are surgeons unanimous with regard to the details of radical cure—first, that the incision should be made directly over the inguinal canal, and secondly, that the hernial sac should be separated from the cord as high as the internal ring and there closed by ligature. But with regard to the next question—Should the canal be opened up by division of the external oblique?—much diversity of opinion has been expressed. Some (for example, Mr. Edmund Owen[3] and Mr. T. H. Kellock[4]) express some fear of weakening the canal by this cause and urge that a cure can be obtained without it. This may fairly be admitted in the case of young boys, though even in them it is easier to deal thoroughly with the sac after the aponeurosis has been divided. I believe, with the majority of writers on the subject, that in order to narrow the canal it is advisable first to open it up as high as the internal ring and that careful suturing of the aponeurosis will leave it as strong as, or even stronger than, it was before. I have met with one case and one only in which the whole anterior wall of the canal bulged after such suturing (with kangaroo tendon). Primary union had occurred and I cannot account for this solitary exception. In the 100 cases quoted the aponeurosis was divided in almost all.

With regard to the method of dealing with the sac two chief opinions are held. Many surgeons *simply* tie the sac at the internal ring and let the stump *retract*; *others twist* and fix the proximal portion in a new position. I am a firm believer in the latter method. If the sac is of average thickness it is brought through a small opening towards the anterior superior spine and secured there (thoroughly twisted up) by a double tendon suture which *transfixes the* muscles and the sac. I have never met with a single case of recurrence at the spot where the twisted sac had been brought through the abdominal wall in *this* manner. If, however, as in some large old herniæ, the sac is very thick I tie it with a Staffordshire knot high up and pass both ends of the ligature on a mounted needle through the muscular wall near the anterior superior spine, subsequently knotting the ends tightly together so as to displace the stump upwards and outwards well under the thick muscles *in this* position. Sir William Macewen's plan of folding up the sac in the subperitoneal space has, I believe, gone out of use, and it appears to have little to recommend it.

Narrowing the inguinal canal.—The late Professor J. Wood was the true pioneer in all that relates to radical cure of hernia, and his contention that it was necessary to restore the valvular action of the conjoined tendon as well as to deal with the sac has been abundantly proved It is shown especially by the greatly improved results that have been obtained since Bassini introduced the *open* method of suturing the conjoined tendon, behind the cord, to Poupart's ligament. For practical purposes the methods of narrowing the canal are only three: (1) Its complete obliteration between the external and internal rings behind the cord (Halsted); (2) narrowing it in front of the cord by sewing down the internal oblique and transversalis (Professor Wood, Sir William Macewen, and others); and (3) narrowing it behind the cord (Bassini). The second method is sometimes wrongly described as obliteration of the canal. All three methods are good, though not one of them absolutely guarantees the patient against all chance of recurrence.

In cases which have been previously operated on, in inguinal hernia in women, and in cases of retained testis where the organ cannot be brought down to the scrotum, the complete obliteration of the canal should be practised. There are some others in which the conjoined tendon is poorly developed and cannot be sutured to Poupart's ligament without undue strain—for these also Halsted's method is advisable.

Of the other two, Bassini's plan—narrowing the canal posteriorly—is probably the most efficient, and it has the endorsement of many surgeons. Of my 100 cases the majority were operated on by Bassini's method; in the earlier ones no formal narrowing of the canal was practised, whilst in about 20 either the canal was obliterated or its anterior wall was tightened up. Of the eight cases of recurrence Bassini's method has been employed in two, Macewen's in one, whilst in five the sack had been twisted and displaced without formally narrowing the canal. This, I think, is conclusive evidence that in adults thorough dealing with the sac alone does not suffice. It should be noted that one patient with poorly developed muscles had a double hernia and recurrence followed operation on both sides, counting as two cases. Another, a case of double direct hernia, recurred on one side only after Bassini's operation had been done on both. A third patient proved to be so unruly and violent after the operation that recurrence of the hernia was only to be expected. Two cases are included as doubtful recurrence; in them no bulging could be made out on examination but the patients stated that it sometimes was present.

It has been urged against narrowing or obliteration of the inguinal canal that orchitis, varicocele, and hydrocele frequently result. In my own cases I could not ascertain that any one of these complications had happened. In one patient the testis was hard and lumpy, but reference to the notes proved that it was in this condition before the operation. In another a slight varicocele was present. When the canal is so narrowed as to injure the vessels of the cord there is undoubtedly a risk of subsequent orchitis or even atrophy of the testis. But I think this can be prevented by observing the effect of the suturing at the time of operation on the circulation in the cord. And unless there is a true varicocele present it is both unnecessary and inadvisable to excise any of the vessels of the cord. In former years when surgeons were given to suturing the pillars of the external ring closely together these testicular complications were frequent, and their free occurrence after the use of silver wire (Bloodgood and Halsted[5]) will be alluded to later.

The material for the deep sutures.—If it be taken as proved that narrowing or obliteration of the canal is advisable in the great majority of cases it follows that the use of deep or buried sutures is a necessity. Although sterilised silk is still employed by a large number of operators I have no hesitation in expressing my preference for kangaroo tendon. Mr. Langton, Mr. G. R. Turner, and others have written in its favour. My own experience of kangaroo tendon goes back to 1890, since which time I have buried in the patients' tissues many thousands of tendon sutures. Unlike silk they hardly ever work out and they can be kept in perfect condition for years in an alcoholic solution of carbolic acid; no material is at once so strong, supple, and non-irritating. It is a delusion to think that they are absorbed in a month or two for I have had occasion to examine such tendon sutures two and three years after I had inserted them. Whilst blending with the surrounding fibrous tissue to some extent they can still be recognised at the end of this time. The fact is the tendon *is not absorbed* but becomes part of the living tissues. Like every other surgeon who has used kangaroo tendon much, I have known a few cases in which these buried sutures have caused suppuration, but as Mr. Langton points out, the trouble is soon over, whereas buried silk or silkworm-gut may sometimes worry the patient with sinuses for *months*. *If the* tendon does irritate it has probably been over-prepared with biniodide of mercury or some other unsuitable antiseptic. It is most important just before the operation to transfer it from the alcohol to sterile cold water, in which it should lie for 20 minutes or so. I cannot understand any operator who has given a thorough trial to the tendon for buried sutures ever being afraid of inserting them or of wishing to change to any other material. Professor Wood used kangaroo tendon in many of his cases and silver wire (which he subsequently removed) in others. Of late years some American surgeons have advised silver wire for all the sutures, buried and superficial. In Mr. Bloodgood's voluminous work on hernia already mentioned,[6] a long series of cases are given in which the canal was narrowed or obliterated by silver wire; in some of them the rectus muscle was dragged down to Poupart's ligament by means of it. The silver wire is supposed by the writer to exert an antiseptic action on the tissues, an action which can only be superfluous if asepsis be obtained. To my mind no region of the body is less suitable for burying silver wire than the groin and its drawbacks were experienced by Mr. C. B. Lockwood,[7] who tried the method in 15 cases with dismal results. In Bloodgood's cases, whatever was the result as regards recurrence of the hernia, the number of troublesome complications recorded is most remarkable. Induration of the epididymis was even referred to as being usual (p. 428) and orchitis followed by atrophy of the testis was frequent. Yet the result in the latter cases was termed "perfect" (p. 480 and elsewhere). Hæmatoma of the scrotum, sloughing of part of Poupart's ligament (p. 427), œdema of the lower limb from obstruction of the femoral vein (three cases), and other complications which could be quoted make up a formidable list which should deter surgeons from using these rigid wire sutures in the radical cure of hernia.

[5] Johns Hopkins Hospital Reports, vol. vii.

The operation on femoral hernia.—I have only succeeded in following up 16 cases for more than two years, 14 women and two men. The average period at which they were last traced was four and a half years after operation, the average age of the patients at the time being 42 years. There were two recurrences—i.e., 12 per cent. In one of these the recurrence took place three years after operation. In the other case the patient was nearly 60 years of age and had chronic bronchitis. She would not have been operated on for radical cure but for the fact that the hernia was strangulated. Although the number of cases is not large it bears out the statement of Mr. Bloodgood[8] that "the cure of a femoral hernia is not a difficult problem."

I have occasionally turned up a flap of pectineus muscle to close the ring, but in the great majority of cases I have twisted and fixed the neck of the sac high up with kangaroo tendon and then sutured with the same material Poupart's ligament to the deep fascia, using two or three separate buried sutures. One has to be careful to avoid injurious pressure on the femoral vein; in one case there was evidence of this, the patient's leg swelling from time to time. In one case of strangulated femoral hernia interesting evidence was obtained of the efficiency of the method alluded to. The patient was an old woman who was suffering from bronchitis, from which she died four days after the operation. At the post-mortem examination I found the femoral ring to be well closed; it resisted firm pressure from above made with the finger.

I have had no personal experience with Roux's method of radical cure—fixation of Poupart's ligament to the pubis by means of a metal staple. Mr. J. Crawford Renton[9] records 25 cases of its use and speaks highly of it. Roux is said to have operated 136 times in this way with only two recurrences of the hernia. The objections that might be raised—viz., that the staple would be liable to work loose and that the femoral vein might be compressed too much—are presumably without much ground. The method seems especially indicated where the femoral ring is widely patent.

One point in the after-treatment of radical cure may here be alluded to—the length of time requisite to secure a sound scar. In both inguinal and femoral cases the wound is, as a rule, soundly healed at the end of a fortnight or three weeks. Is it necessary to insist on the patient resting for more than this time? Some operators, I believe, require two or three months' abstention from work on the part of their patients. But with working men this is a very serious consideration and may mean the entire loss of their previous employment. I see no reason for believing that such prolonged rest is required and have therefore never advised it.

In conclusion, with regard to the radical cure of inguinal hernia the following observations may be made: (1) In all but the simplest cases in children it is best to open up the canal and to narrow it by deep sutures; (2) suturing the conjoined tendon to Poupart's ligament behind the cord by a series of interrupted sutures is probably the best method of narrowing the canal; (3) where the conjoined tendon is deficient, in all recurrent cases, and in inguinal hernia in women the canal should be obliterated; (4) kangaroo tendon is admirably adapted for the suture material, silver wire being probably the worst; (5) recurrence of the hernia *in situ* may possibly take place at any length of time after the operation, but if two years be adopted as the limit it should not occur in more than from 5 to 8 per cent.; and (6) the development of a hernia at another site after operation may be expected in a proportion of cases at least as large as that just given.

Park-crescent, W.

ON THE TREATMENT OF CANCER BY THERAPEUTIC INOCULATIONS OF A BACTERIAL VACCINE,

CONTROLLED BY MEASUREMENTS OF THE OPSONIC POWER OF THE BLOOD.[1]

BY DR. O. JACOBS,
AGRÉGÉ AT THE FACULTY OF MEDICINE OF BRUSSELS;
AND
DR. VICTOR GEETS,
ASSISTANT AT THE INSTITUT ST. ANNE; SOMETIME DEMONSTRATOR OF PHYSIOLOGY IN THE PHYSIOLOGICAL LABORATORY OF THE UNIVERSITY OF LONDON.

THE researches which we have made in connexion with cancer have convinced us: (1) that we have in cancerous cachexia a specific micro-organism, the micrococcus neoformans of Doyen; (2) that the anti-cancerous sera of Doyen with which we have experimented are wholly useless; and (3) that it is practicable to immunise the human organism by means of a series of inoculations of the micrococcus neoformans vaccine provided that these are properly controlled by examinations of the opsonic power of the blood.

In connexion with the first of these subject matters it will suffice to recall to mind that those bacteriologists who, like Metchnikoff, have sought in the different forms of neoplasia for the micrococcus neoformans by the technique prescribed by Doyen have succeeded in finding the micro-organisms, the cultures obtained in the different laboratories being all identical. We ourselves have cultivated the micro organism from 90 per cent. of the tumours examined. Furthermore, we have succeeded in producing localised or generalised neoplasic lesions in 30 per cent. of the cases by inoculating young and vigorous cultures of the micro-organism into mice and white rats. Lastly, as a final argument we shall prove in the course of this paper that the micrococcus neoformans is without doubt the agent of cancerous cachexia.

With regard to the serum of Doyen the clinical results were negative, as our experimental researches made on laboratory animals had led us to expect. This serum was destitute of bactericidal, bacteriolytic, agglutinating, or opsonic power. This serum, had it really possessed the requisite qualities, would have been a precious instrument in the hands of the therapeutist for raising rapidly the defensive power of the cachectic individual; it ought to be discarded.

The vaccines, on the contrary, can give results in careful hands but their inoculation should be made under constant control if it is desired to avoid the bad results which we soon found out when using them. In fact, the vaccines of Doyen are unstandardised vaccines. In view of the principles of immunisation as expounded by Wright we grasped one after another the "why" of the variations, of the mortifications or the negative results obtained by the inoculation of doses of vaccine in the rule-of-thumb manner as advocated by Doyen.

To avoid these accidents we propose the employment of a vaccine made from cultures of the same age, sterilised at 60° C., washed freely, and standardised by the enumeration of the bacilli as advocated by Wright. The antibacterial reaction, which is the method of protection of the body, must be closely watched after inoculation. The method which we have employed is based on the plan of defence employed by the body in its struggle against the micrococcus neoformans. This plan is neither bactericidal nor bacteriolytic—it is phagocytic. This phagocytosis takes place owing to the presence of an element capable of combining with the *micrococcus neoformans* and of preparing it for intracellular digestion. This substance, named "opsonin" by Wright (from *opsono*, I prepare), can be discovered and measured in a drop of blood by means of the technique of Leishman, modified by Wright and Douglas. The blood of all our cancer patients was found below normal with respect to its opsonic action upon the micrococcus neoformans; and the opsonic index undergoes variations in strength after each injection of the micrococcic vaccine. The selection of the dose of vaccine and of the appropriate times for the inoculations was based on the examination of the alterations in the opsonic power of the blood. These variations have been carefully studied for a year in all patients subjected to the vaccine treatment and we wish to lay before you the experience gained by us with regard to the rational treatment of cancerous patients.

[1] Synopsis of a paper communicated to the Royal Belgian Academy of Medicine on Jan. 27th, 1906.

The general conclusion which emerges from our study is that in certain cases the vaccine can do much, in others it can do nothing. Just as a tubercle vaccine judiciously administered does not cure all tuberculous cases, so a "cancer vaccine" cannot cure all cancerous cases. This question of success or failure in cases apparently alike depends entirely upon the reserve of vital energy and the capacity for reaction which each patient possesses, and this differs in each case. With regard to the immunising we can express a definite prognosis after two or three injections of the vaccine, the alterations effected in the quantity of the opsonins expressing accurately the strength of the auto-protective reaction. For example, when the opsonic index does not rise after one or two injections the case is irremediably lost, the immunity has fallen to the lowest degree, the defensive powers seem exhausted and cannot be stimulated by anything. Continued injections in such cases can only hasten the death of the patient, since each injection of the vaccine removes a certain amount of the protective substances, and as no phase of manufacture, no positive phase, succeeds to this, we only set up a dangerous cumulation of negative phases, leading the patient to an early death.

Let us now consider what occurs in the most favourable cases after an appropriate dose of vaccine has been inoculated. Let us imagine a cancerous patient the examination of whose blood reveals an opsonic index below normal, say, 0·7. An injection of the vaccine is now made. A blood examination undertaken several hours later shows a more or less marked negative phase, more or less transient, with the auto-protective power of the blood lowered to 0·5. Two days later a positive phase succeeds it; an abundant production of protective substances has occurred, the blood possesses defensive powers superior to those met with in the normal individual, and the opsonic index has risen to 1·2. This remains constant for a variable time and then shows a tendency to return to its former level. The time has now come to intervene with a second injection. This done we again see the succession of negative phase, positive phase, plateau of increased protective power, and subsequent descent; with this difference, that the lowest level to which the opsonic power is reduced in the negative phase is 0·8, while the immunity in the positive phase is raised to 1·8, nearly double the normal strength of the blood. These fluctuations in the protective power of the blood have been described by Wright in the phrase "ebb and flow and reflow and maintained high tide of immunity," and again in the phrase "cumulation in the direction of the positive phase." When the curve of immunisation follows this course the patient is one in whom the cancerous development seems arrested. Locally, the surrounding infiltration decreases, the cancerous nodules are reduced to their actual size, the tumour seems to fade, and the skin loses its inflamed appearance. In the case of intra-abdominal tumours this improvement is manifested by the fact that the tumours become moveable and by the fact that their limits can now be defined. The general condition is rapidly modified and the most striking fact observed at the beginning of the treatment is that the patient loses his cachectic colour, the pain is diminished, and, in short, the disease seems to be arrested. This is the time when surgical intervention is likely to be successful if the disease is situated in an organ which is removeable. We advise that this interference should, as formerly, be as extensive as possible, for it cannot be doubted that symbiosis with a mass of newly formed—shall we say teratological?—tissue must go hand in hand with the elaboration and absorption of products injurious to the organism.

To take away a neoplastic mass is to suppress a constant source of cellular toxins in an organism which is already painfully struggling against an infection which is infiltrating everywhere. It is quite evident that we cannot expect an anti-neoplastic vaccine to cause softening or complete disappearance of large tumours in a few days and even supposing that it were possible to bring about a necrotic change in a large tumour the organism would not be capable of dealing with and eliminating more than a limited quantity of the products of such cellular metabolism. It would succumb to the harmful effects of an excess of this cellular débris. We cannot demand a therapeutic method to perform more than it can reasonably be expected to do. If it is capable only of holding in check a disease otherwise confessedly incurable we ought, therefore, to employ it as early as possible. We have more chance of success in our attempts to produce active immunisation if we take the disease at the start, when the patient still has much undeveloped defensive power which otherwise would be used slowly and uselessly in such an unequal and insidious contest as is waged between the organism and the invading neoplasm.

Unfortunately, our task is the most difficult, because the patients almost always come to us in a more or less advanced cachectic condition; only with comparatively few can we produce the curve of immunisation which would lead to their cure. What should we do in such cases? The examination of the blood will assist us. The lower the opsonic index the more cautiously should we proceed by inoculating the smallest initial dose of vaccine so as to avoid too marked a negative phase. As soon as a positive phase is obtained reinoculation is to be resorted to only when that curve begins to decline. We had, in point of fact, in the days before we instituted the method of control which now guides all our operations, recognised that patients who appeared to improve markedly at the beginning of the treatment presented, when the treatment was pursued, a sudden aggravation of their local and general condition—an aggravation which was in every case definite and incurable.

To present a concrete picture of the events which supervene upon inoculations conducted as we now conduct them we shall sum up observations on a few patients showing the different results observed in cases as they present themselves in practice.

1. *Case treated solely with a neoformans vaccine showing a typical immunisation curve.*—A patient, aged 56 years, under the care of Dr. Degueldre of Anvers, came to us 12 months ago suffering from inoperable cancer of the rectum with signs of profound cachexia in addition to constant functional troubles. On admission her opsonic index was found to be 0·7. The vaccine injections immediately started, safeguarded by inoculations as explained above, gradually raised the protective substances of the blood to 0·8, 0·9, and after several months to 1·2, 1·1. To-day the patient has no symptom beyond slight constipation. The general condition is excellent; the characteristic complexion has disappeared, giving place to a perfectly normal appearance. Rectal examination reveals an indurated ring situated high up, quite mobile; this is all that remains of the enormous immoveable mass found before the treatment. The present lesion has remained stationary for more than ten months.

2. *A case treated with therapeutic inoculations of a neoformans vaccine and surgical interference; typical immunisation curve and "cure."*—The patient, aged 64 years, was suffering from cancer of the body of the uterus with very pronounced cachexia. Six weeks before we saw her she had undergone a palliative operation, performed by Professor Kufferath. The blood examination revealed that the opsonic index was below normal—0·65. Three vaccine injections were administered which brought up the opsonic index from 0·65 to 0·9. At the same time the general condition was improved; the uterus became moveable and justified a radical operation which had been considered impossible three weeks previously. Since the operation the opsonic index has risen above normal and we confine ourselves at present to maintaining the defensive properties of the blood at this level by injections at long intervals. The

covered by a few flattened epithelial cells and resting on the submucosa of the conjunctiva, which latter shows no evidence of infiltration. The cells of the nodule are arranged in large alveoli and are mostly small with a large nucleus. At the centre of each alveolus are some large epithelial cells. The tumour is non-pigmented and contains a few small blood-vessels resembling capillaries. Diagnosis: The tumour is no doubt a congenital mole. *Recurrent growth.* The tissue consists of the whole thickness of the conjunctiva, in the deeper tissues of which is a small round nodule. This nodule consists of cells resembling the smaller cells of the primary tumour. The nodule is not encapsulated and in one portion the cells are infiltrating the surrounding tissues. The conjunctiva is more vascular than usual. There are no definite blood-vessels in the nodule. Diagnosis: The tumour now is undoubtedly sarcomatous.

Unquestionably these reports show the tumour to have been an alveolar sarcoma, for although the primary growth microscopically is described as a mole it was no doubt clinically becoming a sarcoma—at least, the rapid increase in size noticed by the mother indicates this in all probability.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

ROYAL EAR HOSPITAL, SOHO.

A CASE OF CHRONIC SUPPURATIVE OTITIS MEDIA WITH CHOLESTEATOMA; RADICAL MASTOID OPERATION; COMPLICATIONS; HERNIA CEREBRI; TEMPORO-SPHENOIDAL ABSCESS; MANIACAL DELIRIUM OF LONG DURATION; RECOVERY.

(Under the care of Mr. MACLEOD YEARSLEY.)

FOR the notes of the case we are indebted to Mr. J. Arnold Jones, house surgeon.

A youth, aged 18 years, was first seen by Mr. Yearsley at the Royal Ear Hospital on Sept. 27th, 1905. The patient was suffering from a chronic discharge from the left ear of about five months' duration. He was sent by Mr. J. Blackwood of Southsea, under whose care he had been for some time and who some three weeks previously had removed polypoid tissue from the meatus. On examination a perforation was seen in the anterior part of Shrapnell's membrane through which a fœtid discharge issued. The watch could not be heard at all by the left ear and the tuning fork showed Rinné negative with bone conduction diminished by eight seconds. The patient complained of slight vertigo and vertical headache.

A thorough course of irrigation with perchloride solution (1 in 2000) and the instillation of hydrogen peroxide was the line of treatment at first adopted, but no improvement ensuing it was decided to perform the complete post-aural operation. This was done on Nov. 9th by Mr. Yearsley, assisted by Mr. A. Logan Murison, chloroform being administered by Mr. J. H. Chaldecott. The usual incision was made, the upper and posterior portions of the cartilaginous were separated from the bony meatus, and the whole ear was turned forwards. The antrum was then approached with a hand gouge and discovered to be much dilated and full of foul cholesteatomatous masses. There was a large hole, something under the size of a threepenny-piece, in the tegmen antri with a ragged tear in the dura mater through which a small knuckle of congested brain protruded. The "bridge" of bone between the antrum and the tympanic cavity was removed, a Körner's flap was cut in the cartilaginous meatus, the cavity was packed with gauze, the incision was sewn up, and the usual dressings were applied.

During the next three days the patient appeared to be comfortable and doing well, still, however, exhibiting a certain childishness or simplicity of manner which had been noted on his admission. The temperature, which was 99° F. on admission, oscillated between that and 99·6°. The pulse was 84, regular, and strong. On Nov. 13th the temperature became 101·4° and the first dressing was done. The post-aural wound was sound but there was a rather foul discharge from the meatus. Hydrogen peroxide was instilled and the cavity was syringed through the meatus with perchloride solution. On the 14th the temperature was normal; the wound was again dressed, the discharge being about the same. The general condition of the patient was quite good. The dressing was now done every day in the same manner; the discharge persisted, the temperature varying from normal to 100·6°. On the 18th, in the evening, the temperature reached 102°. The patient complained of headache and cold feet. The pulse was 84, strong, and regular. There were no ocular or other localising symptoms. On the 19th the temperature remained high and the dressing was very foul, the headache became worse, and the patient began to be restless. On the 20th the temperature at 11 A.M. was 102·8°. The patient had developed pains in the neck and back, the headache persisted, but the discharge, although still free, was sweeter in character. The tongue was very furred in spite of good action of the bowels resulting from aperients. The general appearance was quite good. There were no localising symptoms. The pulse was 92, strong, and full. He was ordered ten grains of calomel. On the 21st the patient seemed to be somewhat better. He was not so restless and the pains in the neck and back were less. The dressing was comparatively sweet but not so free. The temperature was 101°. Towards 8 P.M., however, he became much more restless. He did not respond very readily to questions and began to cry out loudly and frequently. 40 grains of potassium bromide having no effect five minims of morphine were ordered to be injected, but this and a further three minims only procured two hours' sleep.

On Nov. 22nd the patient appeared to be worse. He was more emaciated, his mouth was dry and ulcerated, and his tongue was very furred, although the bowels were freely acting. The pulse was 92, full, and strong. The temperature was 102·2°. At frequent intervals he uttered a curious animal cry; there were no localising symptoms of any kind. His knees were drawn up and the muscles of the legs were rigid. He apparently recognised no one and took no notice when spoken to. He was seen by Mr. Yearsley and Mr. R. Lake in consultation and further operation was decided upon. This was done the same afternoon by Mr. Yearsley, assisted by Mr. Lake and Mr. R. S. Cooke. Chloroform was administered by Mr. Chaldecott. The wound was reopened and the antrum was found to be filled by a gangrenous hernia cerebri. This was shaved off and a quantity of foul pus escaped. An abscess in the temporo-sphenoidal lobe was discovered of about the size of a walnut; this was evacuated and washed out. A large double drainage-tube was inserted. The post-aural wound was left open and the usual dressings were applied. After the operation the temperature at 6 P.M. registered 100·5° and the patient remained quiet until about 7 P.M., when he once more became very restless and more boisterous than ever; an injection of morphine (one-quarter of a grain) was given which, with one drachm of potassium bromide, kept him fairly quiet until 7 A.M. on the 23rd when he became uncontrollably noisy. The morphine (one-quarter of a grain) was repeated and again his delirium was held in check. At 2.15 P.M. he was dressed under ethyl chloride anæsthesia administered by Mr. Chaldecott. The tubes were irrigated with boric lotion but, with the exception of some organised clot, very little discharge came away. The temperature at 6 P.M. was 99°, the pulse was 92, and the respirations were 20. The patient again becoming very restless one drachm of potassium bromide every hour until he was quiet was ordered, but this having little effect after six drachms had been administered, an injection of a quarter of a grain of morphine was given and repeated in three and a half hours. In spite of these hypnotics only three hours' rest were obtained during the night, the remainder of the time being spent in tossing about the bed, shouting at intervals his curious piercing cry. The patient all this time took large quantities of nourishment in the form of whey and beef-tea, consuming in the 24 hours 35 ounces of the former and 13 ounces of the latter.

On Nov. 24th the patient slept all the morning, with the exception of an hour. At 2 P.M the wound was again dressed in the same manner as the previous day; it was in the same condition. The temperature varied from 99° in the morning to 101·2° at night. 30 grains of chloralamide, followed in three hours by eight grains of veronal, procured him five hours' sleep during the night. On the 25th he appeared weaker and more emaciated: he was still restless, though calling out at longer intervals and with a feebler cry. The pulse was 108, weaker, but irregular. The highest temperature was 101°. The wound was dressed under ethyl chloride anæsthesia. The tubes were removed. An offensive discharge came away. Gauze packing was inserted.

The patient now continued to become progressively weaker and more emaciated, though still restless and crying out, having little sleep in spite of the exhibition of chloralamide, veronal, and potassium bromide in large doses. He remained unconscious of his surroundings. At 2 P.M. on Nov. 27th he became more sensible, answering when spoken to, but with delayed cerebration, having to be kept rigidly to the point. On the 28th a gangrenous hernia cerebi was discovered in the cavity and excised, the healthy brain tissue being kept in the middle fossa of the skull by packing a piece of tinfoil against it with gauze. The pulse now became much weaker in character, easily obliterated, and varying in rate from 90 to 110, and somewhat irregular. His restlessness and noisiness became more difficult to control, chloralamide, veronal, potassium bromide, chloral hydrate, and morphine in large doses, separately and together, producing little result.

On Dec. 1st the mother for the first time admitted a definite family history of insanity. The exposed portion of the hernia cerebri being now covered with granulations the tinfoil was discontinued, the whole cavity being firmly packed with iodoform gauze after the usual cleansing with antiseptic lotions. During the next three days the patient lost still more weight, becoming very weak and emaciated though continuing his noisy delirium unabated and very little controlled by drugs. From 2 P.M. on Dec. 1st to 2 P.M. on the 2nd he was given two drachms of potassium bromide and 40 grains of chloral hydrate and two and a quarter grains of morphine by subcutaneous injection. All this time he was taking large quantities of nourishment in the form of milk, whey, and beef-tea. The temperature, which had shown daily variations between 99° and 101·8° until Nov. 27th, began on that day to fall gradually, remaining about normal during Nov. 30th and Dec 1st. On Dec. 2nd and 3rd it again rose, reaching a maximum of 99·8°, falling to normal on the 4th, to remain at that level during the remainder of his illness.

On Dec. 4th the patient's condition had reached its lowest limit and he was considered to be beyond recovery. He was taking much less nourishment, was extremely feeble and wasted in appearance, although unabatedly noisy and at times spasmodically violent. The pulse was 92, weak, and thready. The dressing for the first time was done without an anæsthetic, his general condition being deemed too bad. 30 grains of sulphonal and two drachms of paraldehyde were ordered; during the night he had further nine drachms of the latter drug, this combination producing the quietest night he had had since the second operation. On Dec. 5th the patient was a trifle better and was again dressed without an anæsthetic. This improvement was steadily maintained during the next couple of days, he took more nourishment, and passed comparatively quiet nights on large doses of paraldehyde. On the 8th he was very markedly better physically, while mentally he was more sensible than at any time since the second operation. The pulse was more full and steady. Very little discharge now came from the wound and the cavity was lined with healthy granulations. With some short lapses into noisy delirium he now progressed satisfactorily and on the 10th was allowed a little fish. On the 12th his mental condition showed a very decided advance; he talked quite sensibly, recognised the people about him, and answered questions with reason but somewhat delayed cerebration. He was taking very large quantities of food in the form of fish, minced meat, bread, and milk. On Dec. 14th it was found possible to discontinue all hypnotics. On this date, also, it was decided to close up the post-aural wound and to pack the cavity through the meatus. Chloroform and ether mixture was administered. The edges of the wound were pared, freshened, and united with interrupted sutures. An incision to relieve tension was made parallel and posterior to the original one. The cavity was packed through the meatus with iodoform gauze and the usual dressings were applied. From this time onwards the patient's progress was one of steady and uninterrupted improvement. The ear was dressed every day and on Dec. 17th he was up for a short period.

On Dec. 21st the patient was discharged from the hospital in a very satisfactory condition. There was still a little discharge from the post-aural wound and some through the meatus. He was sent back to Southsea under the care of his medical adviser, Mr. Blackwood, who has from time to time given information as to his continued and steady progress.

Remarks by Mr. MACLEOD YEARSLEY.—There are several points of interest in the above case. When first seen in September no indication of the condition in which the mastoid antrum must have been was given either by the symptoms complained of or by the signs observable. The fact that there were slight vertigo and headache was only elicited by questioning and these symptoms were unaccompanied by nystagmus. Perforations in Shrapnell's membrane that do not respond to careful treatment are, however, always to be regarded with grave suspicion, and the radical mastoid operation was recommended when on the second examination, about one month later, the condition was found to be unchanged. Even then the case did not appear urgent and consequently a month elapsed before the exigencies of a small special hospital allowed of his admission. A subsequent letter from Mr. Blackwood contained the information that for a week before admission the patient exhibited a peculiar irritability of temper and slight restlessness quite unlike his usual disposition. The small knuckle of brain seen at the first operation was noticed to be much congested and it is highly probable that the condition of encephalitis which subsequently gave so much anxiety was already begun. I had hoped that the careful packing up of the meatal flap would have barred the communication found between the antrum and the cranial cavity, but this failed.

Another point of interest was the entire absence of localising symptoms when the intracranial complication manifested itself. The most careful examination failed to discover any indication of the condition and retinoscopy revealed nothing. This was doubtless due to the fact that the hole in the tegmen antri and dura mater prevented any intracranial pressure, but it is interesting to note that at no time was there a "cerebral" pulse, Cheyne-Stokes respiration, tache cérébrale, or any other of the classical signs which might have been expected. Further operation was, however, an obvious necessity. Although the cerebral hernia then found was in a state of gangrene, the discharge had become quite sweet for the two days previous.

The subsequent history of the case is most instructive, especially as regards the large amount of nourishment taken and the enormous quantities of hypnotics that were required to keep the patient even moderately quiet. In the 24 hours between 10 A.M. on Nov. 26th and 10 A.M. on the 27th the patient took 72 ounces of milk and whey with ten ounces of beef-tea, whilst in several other periods of 24 hours the amount was not far short of this. On the night of Nov. 23rd he took six drachms of bromide of potassium in one-drachm doses and then required half a grain of morphine to induce quiet. On Dec. 3rd he received two and three-quarter grains of morphine in half and quarter-grain doses, whilst on Dec. 5th no less than ten drachms of paraldehyde with 30 grains of sulphonal had to be administered. Probably the extraordinary capacity for hypnotics was due, or partly due, to the encephalitis. In cases of cerebral complications accompanied by excitement it is always difficult to obtain sleep or to allay the delirium and restlessness, but I have never yet met with one in which such enormous doses of hypnotic drugs have produced so little effect.

In such cases as this recovery is largely due to assiduous nursing and I must pay tribute to the unremitting patience and care with which the house surgeon, Mr. Jones, and the special nurses in charge of the case performed their arduous duties.

Remarks by Mr. CHALDECOTT.—From an anæsthetic point of view this case afforded a valuable illustration of the usefulness of ethyl chloride for cases in which rapid induction of anæsthesia is essential. On several occasions it was necessary to dress the wound under an anæsthetic, the patient being at the time wildly maniacal; in the circumstances gas and ether were contra-indicated and owing to the patient's struggles it would have been a matter of some difficulty and danger to induce anæsthesia with chloroform. On each occasion, therefore, I commenced the administration with ethyl chloride, which acted with great rapidity, the patient's struggles ceasing after two or three inspirations, the ethyl chloride being then discontinued and chloroform substituted.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Value of a Serum (Doyen's) in Cases of Malignant Disease.

A MEETING of this society was held on March 27th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Dr. A. PAINE and Dr. D. J. MORGAN communicated a paper on the Value of a Serum (Doyen's) in Cases of Malignant Disease, which will be found at page 955 of our present issue.

Mr. E. SETON PATTISON said that he had had two cases under his care which had been treated by Doyen's serum, in both of which improvement had taken place but the result had not been permanent. The first case was that of a man, aged 63 years, who had been a great smoker and had suffered from leucoplakia of the tongue for several years. In 1904 he developed extensive epithelioma of the tongue, both sides being involved. The breath was offensive, blood-stained mucus dribbled from the mouth, and the patient was emaciated. Pain was very severe and radiated in all three divisions of the fifth nerve. This patient was treated by Doyen's serum in Paris. After four injections the pain was much less and the general condition improved. After one month's treatment the patient had gained flesh, was able to take food well, and the pain had almost gone. About this time small brown sloughs came away from the growth, and in March, 1905, a large slough came away which caused bleeding from the lingual artery. As this could not be controlled both arteries had to be tied. The tongue became pinkish white in colour and the growth smaller. The improved condition was not long maintained, for the patient developed patches of growth on the gums and died in December. The second case was that of a woman who four years previously had had extirpation of the uterus for malignant disease. A tumour developed in the abdomen which on exploration was found to be malignant. The patient suffered greatly from constipation and from attacks of pain in the abdomen and vomiting. Injections of serum were now given and during two months the patient had 24 injections. She gained weight and improved greatly and her constipation was relieved after, as she said, "something had given way inside." She returned home greatly improved but died shortly afterwards. In another case of malignant disease of the breast, after injections of serum, the growth seemed to be retarded but the patient was not otherwise improved. In another case of recurrent cancer of the breast pain was relieved by the injections but the growth was not arrested.

Mr. CHARLES RYALL referred to the psychical effect produced by the serum and said that this was far greater in Paris, where the patients went to receive injections which were to cure the disease, than at the Cancer Hospital, where the patients knew that they were receiving injections of serum which were being tried experimentally. The symptoms produced by an over-dose of the serum appeared to be very similar to those produced by injections of Coley's fluid. He referred to the case of a malignant tumour of the breast which had been treated with serum and in which subsequently the growth was removed; this he considered a most suitable case for investigating the efficacy of the serum but it failed to produce a favourable result.

Mr. J. HOWELL EVANS said that periods of exacerbation and amelioration almost always occurred in the course of any malignant growth and if the injections of serum were administered during a period of amelioration the improvement would be attributed to the serum. It was most important to bear this in mind when considering the case. Pain again varied considerably and the effect of emotion was often very marked. A word of encouragement would frequently improve the physical condition of a patient in a very striking manner.

Mr R. H. J SWAN referred to the case mentioned by Dr. Paine of recurrent nodules at the back of the neck. He had examined the growth before and after treatment by the serum and the appearance was exactly the same in each case. He would have thought that if the serum produced any effect the appearance of the growth would show some change after the injection. With regard to the case mentioned by Mr. Pattison, in which the lingual artery was tied, he su gested that the improvement was due to the cutting off the blood-supply, and in support of this view he mention the case of a girl in whom a fungating mass in the mou became so much less after ligature of the lingual arte that she was able to swallow solids easily and witho pain, whereas formerly she had only been able to take liqui

Mr. PATTISON pointed out that the improvement in h case had taken place before the arteries were tied.

Dr. PAINE replied.

PATHOLOGICAL SOCIETY OF LONDON.

Pathology of Streptothrix Infection.—Some Experiments Reference to Immunity against Bacillus Pestis—Ther peutic Inoculation in Mediterranean Fever.

A MEETING of this society was held on April 3rd, Profess A. E. WRIGHT, Vice-President, being in the chair.

Mr. A. G. R. FOULERTON read a paper on the Patholo of Streptothrix Infections. At a laboratory meeting of t society held in 1905 he had made a preliminary communic tion[1] on 33 cases of streptothrix infection, and since th six more cases had been investigated. The 39 cases we classified, according to the seat of primary infection, follows: conjunctiva, one case; infection of the tissues the mouth, 21 cases; infection of the lung, seven case infection of the intestinal tract, nine cases, of which fi were cases of appendicitis and four were cases of right ili abscess probably connected with appendicitis; and there w one case of renal streptothrichosis, in which there was history of previous lung disease of some kind. Out of t 39 patients four belonged to the "unoccupied" class a the occupation, if any, was not known in seven case Of the remaining 28 a considerable proportion we from the nature of their occupation specially liable infection from grain and grasses, which had been shown be the natural habitat of several species of streptothriche Thus four were either coachmen or stablemen, two we bakers, two were gardeners, and there was one dairymai Then there was a group of six patients—one tailor, thr tailoresses, and two dressmakers—who would in the cour of their occupation be in the habit of passing cotton-t between their lips. In addition to these 15 patients the were others whose history suggested herbage as a possib source of infection. One patient had spent the sum months in the country and had been in the habit of chew ears of barley and oats; she developed appendicitis wit three months of the end of the holiday. Another patien young man, developed pulmonary streptothrichosis wit three months of a holiday of four or five weeks spent o farm. A third patient, a cellarman by occupation, lived mews. With regard to age distribution there was noth special to note except that there were only two childr under the age of 15 years amongst the 39 patients; five ca occurred in adults whose exact age was not ascertained, t cases occurred at ages between 15 and 25 years, ten at ag between 25 and 35 years, and the remaining 12 cases at ag 35 years and upwards. Details of the cases were then give In all the 39 cases the presence of a streptothrix parasite w proved by microscopic examination and attempts at obtaini cultures on artificial media were made in 30. In 13 cas all attempts at obtaining cultures failed. In four cases scanty growth was obtained in broth only and the precis species present could not be identified, and in the remainin 13 cases the parasite was obtained in pure culture on vario media, so that the species could be identified. Streptothri luteola, which Mr. Foulerton had previously described, wa isolated from the case of conjunctivitis and from an abscess connected with a carious tooth. Streptothrix hominis I., a slowly growing organism which on culture media somewhat resembled bacillus tuberculosis and had also been already described, was isolated from two cases of pulmonary streptothrichosis, from two abscesses in connexion with the jaw, from a case of primary infection of the tonsil with extension to the tissues of the front of the neck, and from an abscess in the substance of the cheek. Streptothrix hominis II., an organism somewhat resembling species I., but growing rather more freely and differing in its pathogenicity for lower animals, was isolated from the case of abscess of the tongue. Streptothrix hominis III. and IV. were two distinct species of free growth and of the same type as the common streptothrix of cattle: species IV. had been isolated from two cases of appendicitis and from one case of right iliac abscess and species III. was isolated from the case of renal streptothrichosis.

---

[1] THE LANCET, May 6th, 1905, p. 1200.

Captain S. R DOUGLAS, I.M.S., described some experiments in reference to Immunity against Bacillus Pestis. He said that in view of the work of Professor Wright on antityphoid vaccination, in which he showed by means of blood tests that excessive doses of vaccine produced very prolonged "negative phases" and in many cases the output of antibodies in the cases where the excessive doses were employed was less than in those cases in which a smaller dose had been used, tests were made to ascertain if this was true for plague. Doses of 0·1 cubic centimetre, 0·2 cubic centimetre, 0·5 cubic centimetre, 1 cubic centimetre, and 3 cubic centimetres of plague vaccine made from an eight weeks old broth culture killed at 65° C. to which 0·5 per cent carbolic acid had been added were given to a series of rats. The best results were obtained with doses from 0·2 cubic centimetre to 1 cubic centimetre. It had been thought that the immunising substance of plague vaccine was contained in the sediment of the vaccine and that the clear supernatant fluid was practically inert. He examined three vaccines; in the first two he showed that the immunising substances in the filtrate were in greater abundance than in the sediment, whilst in the third vaccine the filtrate was almost equal to the sediment. A large number of experiments were undertaken to ascertain if a virulent culture of plague was necessary to obtain an efficient vaccine and it was found that in the case of vaccines made from broth cultures and those made by emulsifying agar cultures in 0·85 per cent. salt solution an extremely efficient vaccine could be made from cultures so non-virulent that the growth from three agar tubes failed to kill a rat when inoculated subcutaneously. Captain Douglas then dealt with the standardisation of plague vaccine by means of the sediment. He showed that the sediment was made up of many variable constituents, and if the weight of the sediment was to be used as a method of standardisation every precaution should be taken to have everything, including the media culture, the temperature, and sterilisation, as parallel as possible. Further experiments were undertaken to ascertain if any information of the amount of immunising substances of the supernatant fluid could be obtained. This was done by estimating the different amounts of precipitate which were present in various vaccines when the supernatant fluid was mixed with an equal amount of highly immune horse's serum. The most suitable dose of plague vaccine for man, as shown by Professor Wright, could most easily be estimated by the examination of the blood of the immunised man after inoculation with a properly standardised vaccine. It was therefore necessary to ascertain if any antibodies against the plague bacillus could be measured accurately enough for this purpose and in consequence the opsonic power of three normal men was estimated for some days to find if this power could be measured with a fair amount of accuracy. After an interval of five days two of the individuals received a dose of one cubic centimetre of a vaccine made from a six weeks old broth culture. In both cases the symptoms following the inoculation were severe, lasting almost a week in his own case, in spite of the fact that the dose given was only one-fifth of that which is usually recommended. It was noticed, however, that the opsonic power of the blood showed no diminution, even on the first day, but rose steadily, reaching its maximum of three times the normal on the ninth day and then rapidly reaching the normal again on the twelfth day. A large number of estimations of this sort would have to be carried out to ascertain the dose

Staff Surgeon S. T. REID, R N., read a paper on Therapeutic Inoculations in Mediterranean Fever. He said that the opsonic power of the blood gave a means of accurately regulating the dose of the vaccine to be inoculated. He then described the technique for estimating the opsonic power of the blood for Malta fever. The dose given was from one-sixth to one-third of a cubic centimetre—about 600 000,000 micrococci Melitenses. In most cases the temperature was raised and this corresponded to the negative phase, but never lasted more than 48 hours. In nine cases a fall of temperature was the chief benefit of the inoculations. In four the decrease of temperature was accompanied by a relief of pain. The nutrition of the patient greatly improved; a setady gain in weight was recorded amounting in many cases to at least half a pound a day. In one case a patient gained nearly 30 pounds in a little over a month. He showed by charts the great benefits which resulted from inoculation and said that if the naval and military authorities could be induced to adopt this method of prevention of Malta fever it would lead to a saving of many lives and preserve the health of the troops in that Mediterranean island.

CLINICAL SOCIETY OF LONDON.

Treitz's Hernia complicating Gastro-enterostomy.—Right Duodenal Hernia in an Infant.—Enormous Cyst of the Common Bile-duct.—Cases of Gastro-jejunostomy.

A MEETING of this society was held on March 30th, Mr. H. H. CLUTTON, the President, being in the chair.

Mr. A. E. J. BARKER read an account of a case of Treitz's Hernia complicating Gastro-enterostomy in a patient aged 50 years. On opening the abdomen with a view to doing gastro-enterostomy for carcinoma of the stomach no small intestine was found within the peritoneal cavity. At first this was difficult to explain, but when it was seen that the colon was higher up than usual and that the anterior layer of its mesentery was bulged forward, the position of all the small intestine behind the latter and a Treitz's hernia was recognised. The relation of parts rendered it necessary to open the sac of the retroperitoneal hernia in order to examine the posterior aspect of the stomach with a view to retrocolic gastro-enterostomy. In the sac was all the small intestine. The stomach was too extensively infiltrated with cancer for the anastomosis. Mr. Barker commented on the difficulties which would be met with in such a case in completing a gastro-enterostomy. Fortunately these cases were comparatively rare.

Mr. E. P. PATON read an account of a case of Right Duodenal Hernia, in which the hernia was reduced but death followed in seven days, due apparently to gut re-entering the sac. The patient was an infant. aged three months. The illness started suddenly with symptoms similar to those of intussusception. A swelling could be felt in the abdomen Laparotomy revealed a considerable length of small intestine which appeared to be engaged under a peritoneal band. This gut was drawn out. No further investigation was possible owing to the general condition of the child. The patient was at once relieved by the operation but was taken suddenly worse on the seventh day and died. At the post-mortem examination a right duodenal hernia was found into which a considerable quantity of gut had returned, which, however, did not seem to be strangulated. There was no peritonitis. The paper was illustrated by photographs and also by the specimen which was now preserved in the Museum of the Royal College of Surgeons of England.—Mr. FREDERIC S. EVE related the case of a woman, aged 64 years, in which he had met with a duodenal hernia during the performance of a colotomy for chronic obstruction.

Mr. EVE read a paper on Large Cysts of the Common Bile-duct. A woman, aged 46 years, was admitted to hospital in November 1902, with an abdominal tumour and jaundice which had existed for three years The tumour extended from the right costal margin to the iliac crest and across the abdomen to the left of, and below, the umbilicus and was evidently elastic. It was thought to be a cyst of the pancreas. At the operation the cyst was opened and it was attached to the parietes. It contained seven and a half pints of clear fluid and pieces of grit, and chemical examination showed bile pigment and cholesterin. The fistula remained open and seven months later a communication was made between the cyst and the hepatic flexure of the colon (choledocho-enterostomy). The patient recovered from the operation but died two weeks later from progressive emaciation and exhaustion. At the necropsy the abdomen was found to be normal with the exception of the large cyst of the common bile duct, which was four and a half inches in diameter. The junction with the colon was firm. Within the cyst and just above the papilla was a papilloma which had acted as a ball valve. Commenting on recorded cases Mr. Eve did not think that the condition was extremely rare, for in only a cursory examination of records he had found 24 cases. As regards causation the cases fell into three groups: (1) those in which the obstruction was due to a vascular formation, to stenosis, or to obliteration; (2) obstruction due to calculus; and (3) obstruction by a growth. Only one case besides that recorded had been found. In the great majority of cases the cyst had been opened and drained, with the exception of those, including Mr. Eve's, with a fatal result which was mainly due in this case to progressive emaciation and weakness from persistent jaundice. Some cases had been treated by uniting the cyst with the duodenum, the jejunum, or the colon. Mr. Eve thought that this was a matter of choice and in the majority of cases the colon was indicated on account of the extensive adhesions and the alteration of relationship of parts.

Mr. F. C. WALLIS read notes of three cases of Gastro-jejunostomy. The first case was that of a female patient, aged 91 years, who made an excellent recovery, losing all the symptoms for which the operation was performed The patient died 12 months later from cerebral thrombosis. The other two cases were both instances in which chronic inflammatory thickening around an ulcer simulated a new growth both in appearance and to the touch. In both cases a posterior gastro-jejunostomy was done. In the one case when the abdomen was re-opened a month later to do a partial gastrectomy the "growth" had almost entirely disappeared and an ulcer on the posterior wall could be felt through the anterior. The patient had quite recovered and had gained weight. In the other case the supposed growth occupied the cardiac half of the stomach. The operation relieved the pain, which was the main symptom complained of, but the patient died on the fourth day from hæmorrhage. The necropsy showed a large ulcer situated on the posterior wall; a large vessel ran along the floor of the ulcer and in the middle of the vessel was an oval opening. Mr. Wallis remarked that the first case illustrated the fact that even very old people stood operations well when their tissues were young. The lessons which he learnt from the other two cases were: (1) that in the majority of cases when partial gastrectomy was under consideration a posterior gastro-jejunostomy should be first performed; and (2) that delays were dangerous in cases of gastric pain which did not readily yield to medical treatment. In such circumstances the abdomen should be opened and the stomach examined. A gastro jejunostomy could be done, and if there had been hæmatemesis to any marked degree the stomach should be opened through healthy tissue in the neighbourhood of the ulcer and the ulcer cut out, cauterised, or ligatured to prevent further hæmorrhage.—Dr. W. HALE WHITE emphasised the fact that old age should not in itself be a bar to even serious operations. He had seen Mr. Wallis's first patient and was much impressed by the relief that she had experienced. The second group of cases was extremely important and he wished to refer in this connexion to masses of inflammatory material arising from the gall passages and simulating new growth by causing pressure on the pylorus. He had seen such a case recently and was convinced of the presence of pus owing to the high leucocytosis present; he had great difficulty in inducing the surgeon to incise the mass which closely resembled cancer, but after evacuation of the pus the patient made a complete recovery.—Dr. F. DE HAVILLAND HALL related a case recently under his care in which great benefit was obtained by simple laparotomy alone.—Mr. W. G. SPENCER referred to the anomalous course often pursued by gastric cancer and warned surgeons against too soon assuming that the diagnosis of cancer was incorrect merely because great improvement followed operation.

LIVERPOOL MEDICAL INSTITUTION.

The Diminishing Birth-rate.—The Position of the Operative Treatment of Fibroid Tumours of the Uterus.—Tropical Abscess of the Liver.

A MEETING of this society was held on March 29th, Mr. FRANK T. PAUL, the President, being in the chair.

Dr. HUGH R. JONES read a note on the Diminishing Birth-rate. Although artificial means of preventing conception were being more generally and systematically adopted it must be remembered that families had always been limited by prudential self-restraint—to an extent not generally realised. The influence of the later age at marriage and the lower marriage-rate and of the employment of women in intellectual and industrial occupations was being underestimated. The death-rate had also fallen and this fall began before the fall in the birth-rate. The former was due in part to the high birth-rate in former years but it also indicated an improvement in the social condition of the population. Improvement in the social status always attended by a fall in the birth rate. The nat increment of the population was still high. The low de rate was masked and compensated for by the low birth-r It was to be regretted that except in 1904 and 1905 the of infantile mortality had been persistently high. He h that the present low birth-rate was only a temporary p in the history of English civilisation, for a high birth- and a robust young population were necessary to cont the past policy of England. The growth of the popula of a country depended on the sustained systematic polic the mass of the people, which was guided by the ac and teaching of the educated classes, and upon them the responsibility.—Mr. COLIN CAMPBELL remarked THE LANCET had recently directed attention to adver ments of "preventatives" in journals such as *Myra's*. had exhibited some years ago samples of preventatives to a midwife to retail to her patients.—Dr. W. MAC Mr. H. H. MOFFAT, and Dr. G. O. WALKER also spoke.

Dr. T. B. GRIMSDALE read a short note on the Opera Treatment of Fibroid Tumours of the Uterus and pointed the wonderful improvements that had been made in a minal hysterectomy of late years and contrasted the mort at present with that of ten years ago. He also showed the mortality from operation was now less than that of disease.—Dr. H. BRIGGS thought the present safety abdominal hysterectomy in the treatment of fibroids a early stage was an encouragement to the gynæcologist the operation could be often declined to the pati advantage.

Mr. G. P. NEWBOLT read a paper on Tropical Absce the Liver, based on cases seen in the tropical wards of Royal Southern Hospital, Liverpool. In all his cases t was a history of dysentery. Amœbæ were found in sloughs from the abscess wall in several instances but once in the motions. The tendency was for the absce point posteriorly through the chest wall. In two pati the abscess opened into the lung and the pus expectorated but it was necessary to drain the abscess f by resecting rib; both cases recovered The mat expectorated was brownish in colour and conta broken-down liver cells. One of these patients three abscesses opened and drained during a period four years but made a perfect recovery. In ano two abscesses were opened during life but a third between them and was not discovered. Mr. Newbolt stress on the importance of exploring with a long need large calibre, and also drew attention to the fact that a with a liver abscess might go about with a normal t perature and without much discomfort, but the pulse usually quickened. He considered it most important the dysentery should be cured before the patient was charged as this disease, although often made light of, at time might cause fresh infection. In one case the dysent pain was so acute that exploratory laparotomy was formed; nothing abnormal was found in the liver and patient was cured by syphoning the large intestine wi solution of nitrate of silver (20 grains to the pint). In cases which recovered the pulse-rate declined directly a the abscess was opened; if the pulse-rate kept up it probable that there were other abscesses present or dysentery was very severe. Experiments in the post-mor room showed that the healthy liver would not hold stitc but after opening the abscess through the abdom wall, in most cases, the liver being inflamed, the stit held, though in one case packing was used for a week p to incision. In operating through the chest wall the abs was emptied with the aspirator and its wall was pulled and fixed to the edges of the superficial wound. Large ru tubes were used for drainage and in some instances abscess cavity was scraped with a blunt lithotomy scoop irrigated. In order to show how rapidly the cavities c up Mr. Newbolt said that eight days after the removal 50 ounces of pus the cavity would only hold four ounce lotion. In one case the liver abscess was tympanitic ow to the escape of gas from the adjoining colon.—Mr. K. MONSARRAT spoke of the difficulties of evacuation satisfactory drainage in cases where the abscess bul directly downwards from the under surface of the right l at considerable depth from the anterior abdominal wall. considered that an incision below the twelfth rib in loin was the only route for satisfactory drainage in s circumstances. He mentioned the case of a woman who h always lived in Cheshire and on whom he had operated fo single abscess in the right lobe. There were no symptoms of any intestinal disorder; there was no fever; the pus was sterile bacteriologically but contained amœbæ in large numbers.—The following members also took part in the discussion: The President, Dr. T. R Glynn, Dr. W. Carter, Dr. Nathan Raw, Dr. R. J. M. Buchanan, Dr. C. J. Macalister, and Dr. J. Lloyd Roberts.

Sir James Barr exhibited a new Hæmomanometer.

Chelsea Clinical Society.—The annual clinical debate of this society was continued on March 20th, Dr. James Barry Ball, the President, being in the chair.—Dr. F. F. Caiger, continuing the discussion on Serum Therapy, said that it might fairly be stated that the antitoxin treatment of diphtheria stood on a well-established basis. In the hospitals of the Metropolitan Asylums Board during the last ten years between 60,000 and 70,000 cases of diphtheria had been treated, with the result that the mortality, which previously had never been below 30 per cent., had been reduced to less than 10 per cent. The actual figures for 1905 had not yet been published, but in relation to the South-West London Fever Hospital the mortality last year came out at only 8 per cent. It would be thus seen what an enormous benefit was shown in the treatment of diphtheria by antitoxin in the public hospitals of London and it was more particularly in connexion with two classes of cases that that benefit had been most found. In the first class of case, the laryngeal group, before the antitoxin days they did not have any better results than a recovery rate of 30 per cent. He believed that he was correct in saying that eight years previously to the introduction of antitoxin the recovery rate averaged 29 per cent. At the present time, owing to the universal application of that remedy, they were quite dissatisfied with a recovery rate of less than 70 per cent. The second group in which the benefit of the antitoxin treatment had been most strikingly shown was in connexion with post-scarlatinal attacks of diphtheria—in other words, patients convalescing from an attack of scarlet fever who had contracted diphtheria. Prior to antitoxin days post-scarlatinal diphtheria was justly regarded as the scourge of the scarlet fever wards and a large part of the mortality was directly due to it; the mortality taking all attacks with the laryngeal or faucial cases worked out at over 50 per cent. and in the laryngeal group it was 80 per cent. and sometimes even reached 90 per cent. What was the effect of the introduction of the antitoxin treatment on these cases? Simply that instead of 80 per cent. or 90 per cent the mortality was now reduced to less than 1 per cent, the reason being that these patients were already under medical care at the onset of the diphtheria and the disease was treated at the very earliest moment. Dr Caiger then proceeded to emphasise the extreme importance of early treatment. The clinical effects which followed the use of antitoxin were a rapid diminution of the faucial swelling and consequent distress, a diminution if not an entire cessation of the offensive discharge from the nose, a limitation of the membrane with its early separation, an improvement in the aspect and general well-being of the patients, and in those cases which died life was prolonged to an extent unknown with any other form of treatment. In his opinion very large doses of the antitoxin were unnecessary. Moderate doses repeated at the end of from 12 to 24 hours, according to the urgency of the case, continued until the membrane showed definite signs of separating, secured as much benefit as ensued with very large doses The dose should be determined by the urgency of the symptoms and by the time at which the patient came under treatment Dr. Caiger concluded by discussing the methods of administration of the antitoxin and described the attempts to treat scarlet fever by curative serum.—Dr. B. L Abrahams, after commenting on the mortality from diphtheria, discussed the serum treatment of typhoid fever In regard to the mortality from typhoid fever the great difference which had come about in the last few years was in his opinion due to the Widal test At the present time directly a case was suspected to be typhoid fever the Widal reaction was tried, with the result that there was an early recognition of the disease with the consequent early treatment of it. Concerning opsonin work Dr. Abrahams said that many of those keen on the treatment of tubercle by means of sera and bacterial products said that if a patient had a high opsonic index he would get better with tuberculin, but statistics showed that a patient with a high opsonic index would still get better without tuberculin, in other words, the opsonin test was excellent in diagnosis, but he was not inclined to think that it was going to be of very great service in treatment.—Dr. Allan Macfadyen said that the successful treatment of diphtheria by antitoxic serum had led to investigations in other directions with regard to the possible production of soluble poisons by other infective organisms. Among those attempts were included experiments in connexion with typhoid fever and cholera for the purpose of procuring the soluble poisons concerned, but the result had been disappointing, because the filtrates of typhoid cultures were only feebly toxic and it was found that, as a matter of fact, in the majority of cases of pathogenic organisms the toxins they had to deal with were not soluble toxins but intracellular toxins. It had to be acknowledged that as regards purely bacterial sera there was still doubt as to their actual practical value. Dr. Macfadyen concluded by saying that with regard to serum therapeutics bacteriologists must endeavour to produce some common factor on the antitoxin basis which would neutralise such toxins as those of the streptococci independently of any individual virulence of the strains which might be present, especially in regard to plague, typhoid fever, and cholera. In that way he thought the great future advances in serum therapy would be made. He was not pessimistic about the matter, for he felt that if research was pursued diligently they would come to some results which would be of value in treatment.

Royal Academy of Medicine in Ireland: Section of Pathology.—A meeting of this section was held on March 16th, Dr. Joseph F. O'Carroll, the President, being in the chair.—Dr. Alfred R Parsons exhibited Kidneys which had all the appearances of the congenital cystic form, only a small portion of the kidney substance being left intact. The patient, a man aged forty years, was in his usual good health until the day before his death. Suddenly becoming ill he was admitted to hospital where he died in 12 hours. Clinically he exhibited symptoms of gastro-intestinal irritation, with suppression of urine. The necropsy revealed nothing amiss except the kidneys shown. The brain was examined and was found normal.—Professor John A. Scott considered the condition as being of the nature of hypertrophic cirrhosis due to a pathological change that must have begun within the last ten years at least.—Professor A C. O'Sullivan showed an Aortic Aneurysm perforating the Pulmonary Artery and causing Perforation of the Pulmonary Valve. The patient from whom the specimen was taken was brought in a dying state to hospital. The necropsy showed an aneurysm of the aorta on the right side, half an inch above the attachments of the valves, and perforating the pericardium. It had also perforated the pulmonary artery above the valves and the valves themselves showed evidence of perforation.—Mr. E. H. Taylor exhibited a specimen of Epithelioma involving part of the Duodenum where the Bile-duct opens into the Intestine. The patient, who was a man, aged 40 years, had had several attacks of jaundice. When he came to hospital his liver was somewhat enlarged and his skin was slightly jaundiced. On opening the abdomen the gall-bladder was found to be distended and a great number of gall-stones were in the common bile duct A hard mass which was discovered in the duct where it opened into the duodenum was removed. On the ninth day the patient's temperature rose and he developed pneumonia, from which he died. At the necropsy a cancerous mass was found at the mouth of the duct. There was no obstruction to the flow of bile and the liver was enlarged and cirrhotic.—Mr. Taylor also showed a specimen of Cancer of the Ovary removed from a woman, aged 55 years. On examination it seemed like circumscribed peritonitis, and could be felt just above the pelvis The patient would soon be able to leave the hospital.—Dr. Wallace Beatty exhibited a boy, aged nearly four years, the subject of Urticaria Pigmentosa dating from a month after birth, and he showed microscopic sections of a nodule excised from inside the knee. He demonstrated the interesting fact that the granules of the mast cells, which were stained red by polychrome methylene blue in alcohol, were stained also by eosin if the skin was fixed in Zenker's fluid (i.e., Müller's fluid saturated with corrosive sublimate plus 5 per cent. glacial acetic acid) before final hardening with alcohol.—Dr. Walter G. Smith said that it was not improbable that the closer study of stains and dyes might throw some light upon the important problem of the nature of proteid substances. He pointed out that an efficient stain usually included, or was made up of, three constituents: (1) a nucleus, or chromophore, with a feeble acid or basic tendency and usually belonging to the aromatic series; (2) auxochromes, represented by NH_2 (basic group), or OH and oxygen (*acidic radicals*), attached to the chromophore; and (3) salt-forming groups, such as COOH (carboxyl), HSO_3, and NOH.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on March 28th, Dr. J. K. Kelly, the President, being in the chair.—Specimens were shown by Dr. Robert Jardine, Dr. John Lindsay, the President, and Dr. A. Louise McIlroy.—Dr. A. J. Wilson read notes on three cases of interest—namely, (1) Apoplexy (?) in a Young II-para; (2) Tumour of the Base of the Skull in a Newly born Infant; and (3) a case of Paternal Influence in Twin Pregnancy. In the first case the patient, while six months pregnant, became suddenly unconscious during the night; there was no history of previous ill-health. A convulsive attack was first observed followed by coma; dark coloured fluid was vomited and there was incontinence of urine. On examination neither œdema nor paralysis was present. Labour was induced and completed and the usual remedies for eclampsia were applied. The coma deepened on the second day, the left arm and leg became paralysed, the urine was suppressed, and death occurred on the fourth day. In the second case, that of a female child, at birth the nasal bones were distended and a cystic portion of a tumour projected from the right nostril. A soft mass covered with skin filled the mouth and projected forwards, pressing the tongue out of sight. The tumour was found to be growing from the naso-pharynx and was attached to the base of the skull. It filled the nasal cavity and passed through a large cleft in the palate by means of a pedicle and then expanded in the mouth into a bilobed mass of the size of an infant's fist. The tumour was removed by operation, the child dying on the ninth day. The microscopical sections prepared by Dr. Duff showed definite dermoid structures. In the third case Dr. Wilson read notes of a woman who gave birth to triplets, followed in 13 months by twins. On the husband's side twins occurred twice in his mother's family; the wives of five uncles each had twins. A short review of recorded cases was given.—Dr. James Weir read a paper on the Resuscitation of Apparently Stillborn Children. He thought that the subject was inadequately touched upon by most teachers of obstetrics and it was one having an influence on the subject of infant mortality. The influence of chloroform was slight unless operative treatment for the mother was prolonged. Dr. Weir in his obstetric practice used A.C.E. or C.E. mixture as being less injurious to the infant than chloroform alone. The method of Schultze was the best for artificial respiration, as in addition to the movements the child's skin came in contact with the varying temperature of the air. Stimulation of the sphincter by inserting the finger into the rectum was often of great benefit in bringing about attempts at respiration. It was also a guide as to the amount of vitality present, a tight sphincter being of good omen.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 8th, Mr. W. H. Date being in the chair.—A discussion took place on Dr J. R. Thomas's paper on Physical Deterioration. In this paper Dr. Thomas had specified 13 causes which in his opinion tended to impair the health of the nation, some of them being the increase in urbanisation, alcoholism, unsuitable food, parental ignorance and neglect of children, juvenile smoking, syphilis, and inattention to the state of the teeth.—The discussion was introduced by Dr. Thomas himself, who said that he wished to obtain help from the society as to whether it was desirable to form a local branch of the Society for Physical Education and Improvement. He then recapitulated some of his points, adding that infant mortality had not diminished in any part of the country. At Huddersfield great improvement had, however, taken place owing to the mayor of that city having offered a reward of £1 to any mother who brought up her baby for inspection at the end of its first year. As to remedial measures, ladies' health societies were useful. It was undesirable that any child under five years should attend school. Helpful girls might be allowed to assist their mothers during the day and attend school at night. The free feeding of children at school was advisable if they were insufficiently fed at home. The State ought to take measures to insure that no children went to school starving.—Mr. R. Coombe then proposed a motion to the effect that this meeting of the Devon and Exeter Medico-Chirurgical Society was in favour of the formation in Exeter of a local branch of the National Society for Physical Education and Improvement. He drew attention to the report of three Members of Parliament as a result of their inspection of municipal arrangements in Berlin. They came to the conclusion that a despotic government directed the populace on better lines than were followed in free England. More direction was required in England and the medical profession should put itself in the forefront.—Dr. P. M. Deas, who seconded the motion, said that he was inclined to consider that the objects of the National Society were too comprehensive. The attention which was now given to the general principles of hygiene led to a survival of the unfit and tended to keep degenerates alive. The true remedy consisted in education as to the production of children and the avoidance of early and improvident marriages.—Other speakers took part in the discussion and the motion on being put to the meeting was carried.

THERAPEUTICAL SOCIETY.—A meeting of this society was held on March 27th, Sir Lauder Brunton, the President, being in the chair.—Dr. J. Gordon Sharp (Leeds) read a paper on Native and other Plants having some Relationship to Curare, including (1) anchusa officinalis, alkanet, an imported plant containing an alkaloid; (2) echium vulgare, viper's bugloss, an indigenous plant containing an alkaloid; and (3) cynoglossum officinale, houndstongue, a common plant containing two alkaloids. All belonged to the Boraginaceæ. Anchusa rendered a frog's skin moist and hyperæsthetic at first but afterwards insusceptible to stimulation, while the stimulus to the sciatic nerves or the muscles themselves caused contraction. The heart stopped in diastole and atropine only produced a few contractions of the left auricle. Echium caused the same symptoms with more hyperæsthesia and greater weakness of the muscles. After a large dose no stimulation of the sciatic nerve caused any contraction, though the muscles reacted to direct stimulation. The heart stopped in diastole. Cynoglossum rendered the skin moist and very hyperæsthetic; stimulation to either the sciatic nerves or the muscles directly only affected the unpoisoned side. It often acted somewhat like curare but frequently death occurred suddenly with the heart in diastole. Among foreign plants the delphinium bicolor and occidentale from North America and the delphinium scopulorum from Mexico resembled somewhat curare. Their extracts were bitter with a slight smell and turned red with sulphuric or nitric acids, though delpho-curarine, their alkaloid, gave no colour with either acid. The extract of delphinium bicolor acted like curare at first, it increased the action of the skin, but in two hours the muscles of the poisoned side only contracted on direct stimulation, though on the unpoisoned side they were acted on by stimulating the sciatic nerve. Delphinium occidentale at first acted like aconite, increasing all secretions, but later the muscles became insensible to any stimulation, either direct or through the nerves. Delphinium scopulorum differed from the others inasmuch as the nerve centres of the cord were greatly depressed, more than the nerve trunks or the motor ends. Delphinium staphisagria or stavesacre first stimulated the secreting organs and the nerve centres, then depressed, and at last paralysed the nerve centres, the motor nerves, the muscles, and finally the nerve centres of the heart.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 17th, Dr. J. Lindsay Steven, the President, being in the chair.—Dr. John M. Cowan read a paper on the Results of the Infectious Diseases on the Vessels. He said that arterial disease might be produced by bacterial causes acting acutely and for a short period. Those acute lesions might be of little importance *per se*, but as places of diminished resistance they might allow the more slowly acting chronic causes to take effect. He showed microscopic sections illustrating the effect of syphilis on the arteries: endarteritis obliterans in the smaller vessels; in the larger the lesion was focal; the intima was thickened and degenerated; the media was slightly atrophied; in the adventitia the vasa vasorum were affected by endarteritis obliterans and around the vessels were little collections of mononuclear cells. The nutrition of the media and intima was thus interfered with. Other specimens showed patches of necrosis in the media—one with calcareous granules and in another the necrotic area was invaded by granulation tissue. Dr. Cowan then showed that the same type of lesion was found in other diseases, such as acute rheumatism and tuberculosis. In enteric fever Thayer found fresh atheroma in 21 out of 52 necropsies. Bacteria had been found in a few such patches and the infection apparently had been directly by the blood stream and not vasal. Small aggregations of mononuclear cells around small arteries were found in the organs in many diseases. These, in some cases, might cause distinct increase of the peripheral resistance and a rise of blood pressure. An irregular arrangement of the elastic fibres of the middle coat of the aorta was another change found in diseases such as pneumonia, pulmonary tuberculosis, acute peritonitis, and enteric fever.—The President read a paper on Certain Clinical Aspects of Arterial Disease. He said that clinically there were two varieties of high arterial tension: (1) temporary and recurrent; and (2) continuous. The first was brought on by excess in diet, by constipation, or by nervous excitement, and could be relieved by the judicious use of aperients and the nitrites. The latter form was associated almost always with chronic renal disease. In both, the exciting cause was the presence of toxic agents in the blood.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held on March 23rd, Mr. E. Ward being in the chair.—Among the cases shown were the following:—Dr. T. Wardrop Griffith: A case of Atypical Leucocythæmia in a boy, aged 13 years.—Mr. W. H. Brown: A case of Traumatic Asphyxia.—Dr. Bedford Pierce: A case of Korsakow's Disease in which there were a 17 years' history of intemperance and evidence of affection of the lateral columns, with marked amnesia and failure of orientation.—Mr. H. Littlewood: A case of Rheumatoid Arthritis of the Knee, in which arthrectomy was performed with benefit.—Dr. A. G. Barrs: A case of Hodgkin's Disease with high lymphocyte count and slight dyspnœa as the only symptom.—Dr. A. Sharp: A case of Pachydermia of the Vocal Cords.—Mr. G. P. Anning and Dr. E. F. Trevelyan: A case of isolated Paralysis of the Extensor Communis Digitorum in a man with a history of lead poisoning.—Dr. T. Churton: Several cases of Metapneumonic Empyema.—Mr. H. Secker Walker: A case of Persistent Hyaloid Artery in both Eyes.—Mr. Michael A. Teale: A case of Monocular Vertical Nystagmus.—Mr. R. Lawford Knaggs: A case of Gangrene of Fingers following injection of spirit of camphor given four inches above the wrist; almost immediately the thumb and three outer fingers became cyanotic and subsequently gangrenous.—Dr. W. H. Maxwell Telling: Extensive Scarring in a case of Generalised Vaccinia.—Dr. Dobson and Dr. Telling: Two cases of Probable Gummatous Ulceration of the Tongue in Children.—Cases were also shown by Dr. J. Gordon Sharp and Dr. A. L. Whitehead.

Reviews and Notices of Books

A System of Medicine. By Many Writers. Second edition. Edited by THOMAS CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.R.C.P. Lond., LL.D., D.Sc., F.R.S., F.L.S., F.S.A.; and HUMPHRY DAVY ROLLESTON, M.A., M.D. Cantab., F.R.C.P. Lond. Vol. I. London: Macmillan and Co., Limited. 1905. *Pp.* xvi.-1210. Price 25s. net.

IN the ten years which have elapsed since the publication of the first volume of Professor Clifford Allbutt's well-known "System of Medicine" naturally considerable advances have been made in reference to most of the subjects dealt with in it and therefore the appearance of a second edition will be welcomed by the large body of workers to whom it has served as an exhaustive work of reference and an authoritative presentation of the position of medical knowledge. From the preface we gather that it is intended to revise and to republish one volume each year and thus gradually to replace the original edition by the new. In the preparation of this present edition Professor Allbutt has the assistance of Dr. H. D. Rolleston whose name now appears on the title page. We may felicitate Professor Allbutt on his choice of a co-editor, for Dr. Rolleston's wide pathological and clinical experience, as well as his literary attainments, render him peculiarly fitted for the task. The success which it has achieved and its unrivalled excellence as a work of reference are a credit alike to Professor Allbutt and his co-workers. Moreover, for conciseness and yet fulness, for convenience of reference, and for comprehensiveness it challenges comparison with most, if not all, of the large works of reference by foreign authors. It has supplied a need, and the appearance of this new edition is timely, for the striking advances of the past decade needed collating and codifying for purposes of reference.

Considerable alterations have been made in the arrangement of the subjects dealt with in this volume, several new articles have been added, others have been transferred to later volumes, and yet others have been modified or extended, with the result that it is larger than its predecessor by over 200 pages. Within the limits of the space at our disposal it is impossible adequately to review this really great work, or even to enumerate the articles or rather monographs which it contains: we must therefore confine ourselves to noting the changes which have been made in it. The introduction by Professor Allbutt with which the first edition commenced has been omitted, which we are tempted to regret (though, no doubt, it has been sacrificed to the exigencies of space) for it was a scholarly, thoughtful, and suggestive examination of the general principles upon which the science and practice of medicine are, or rather should be, based. Its place is, however, taken by an article on the History of Medicine divided into two parts, the first of which deals with medicine in ancient times and is contributed by Professor Allbutt himself in his usual refined, graceful, and instructive style. The second section, by Dr. J. F. Payne, devoted to medicine in modern Europe, is, as might be expected from so eminent an authority, a most able and comprehensive, though necessarily brief, summary of the gradual evolution of the present methods from the darkness, superstition, and ignorance of the Dark Ages. We read with great interest Dr. Payne's account of Sydenham, the "English Hippocrates" as he has been called, and of the originality and genius of his methods. This joint article is a valuable addition to the work and we are glad that Professor Allbutt has modified his view expressed in the preface to the former edition that the story of medicine has been but a melancholy study. This article forms the first in the prolegomena and is followed by one on Medical Statistics by Dr. J. F. W. Tatham in place of that contributed to the first edition by Dr. J. S. Billings. Dr. Tatham's article is thoughtful, lucid, and suggestive, and is illustrated by frequent reference to the mortality tables for various diseases. The influence of occupation on the mortality of certain diseases is also studied.

Dr. F. G. Clemow contributes an article on Medical Geography which replaces that on the Medical Geography of Great Britain by the late Mr. A. Haviland. This subject is one of comparatively recent growth and, as Dr. Clemow points out, it needs to be supplemented by a study of medical history, especially in regard to diseases of an epidemic character. He justly draws attention to the fact that Great Britain has been the pioneer in the study of this important subject and that to British observers are due some of the most striking advances in this department of knowledge.

A new article has been introduced on the subject of old age and is in two parts. The first is by Dr. F. Parkes Weber on the physiology and pathology of old age, in which the chief retrograde changes and histological and other alterations incidental to advancing years are portrayed as they affect the various systems and organs. The second part, by Sir Hermann Weber, deals with the prevention of premature old age and the prolongation of life to its natural term. It is chiefly devoted to the recommendation of simple hygienic and dietetic rules. Sir Hermann Weber's remarks that "the habit of sleeping much—viz., over eight hours—is often more injurious and shortens life more frequently than sleeping only five hours, since it causes diminution of the activity and elasticity of the arterioles of the brain and in consequence a tendency to thrombosis or hæmorrhage or early degeneration of the mental faculties," seem to us an *ex cathedrâ* statement which it would be difficult to justify scientifically.

The article on Dietetics has been considerably altered and a section dealing with the physiological principles of dietetics by Dr. R. Hutchison has been added to it. This constitutes a concise and clear statement of the relative value of foods with the modifications in diet necessitated by various conditions and includes an account of the characters of the principal foodstuffs. In referring to Professor Chittenden's interesting researches on physiological economy in nutrition, Dr. Hutchison expresses the view that further experience is needed before it is proved that his results are true for an indefinite period of time, but that if this proves to be the case the conclusion that the usual dietary standards are too high will be inevitable.

The section on the Feeding of the Sick is contributed, as in the last edition, by Sir Dyce Duckworth. Various modified diets are discussed, including the so-called zomotherapy or raw meat diet, and the indications for them are given. The article on the Principles of Drug Therapeutics, written by the late Dr. D. J. Leech, has been revised by Sir Lauder Brunton and is a very thoughtful and suggestive presentation of the principles of rational therapeutics and the application of pharmacological experience to the treatment of disease.

An addition to the present volume is the important and useful article on Physical Exercises by Mr. E. M. Corner, which is divided into three sections, the first of which deals with the physiology of exercise and is a forcibly-worded plea for a wider application of muscular exercises, especially those of the respiratory system, in our educational system. Mr. Corner says: "In early life our minds are carefully instructed and trained by highly educated men, but our bodies are allowed to develop according to the inclinations of their owners. Exercise is encouraged by all authorities but the use made of the opportunities supplied rests with the individual, who will utilise it or shirk it according to fancy." The second section deals with the actual exercises and systems of exercises which are in use, while the third is devoted to their application to various conditions of disease or deformity.

A further addition to the present volume is an article on the X Rays in Medicine by Dr. Francis H. Williams. It deals with the methods employed and their application in the diagnosis and treatment of disease. The uses of this form of examination in the diagnosis of diseases of the chest are carefully described and clearly illustrated, while the article as a whole is a valuable summary of the present state of our knowledge of the subject.

The article on the General Pathology of New Growths, by Dr. F. W. Andrewes, replaces that on the same subject by Mr. S. G. Shattock and Mr. C. A. Ballance in the former edition. It constitutes a very comprehensive and masterly survey of a most difficult subject and is a most valuable monograph. The cytology of malignant growths and the various theories and explanations of tumour formation are intelligibly presented and critically considered. Dr. Andrewes's article is a noteworthy addition to the literature of the subject. A further addition to the prolegomena is an article on the Clinical Examination of the Blood and its Significance, by Dr. J. H. Drysdale. The various methods for the examination of the blood are carefully described and their indications considered. The article is well illustrated and the varieties of the corpuscles, both red and white, are excellently portrayed on a double-page coloured plate. The directions for preparing the stains employed in the preparation of blood films are clear and practical and the method of using them is given in each case.

The article on Fever by the late Sir J. Burdon Sanderson has been extended by the addition of a section on physiological considerations in regard to fever by Dr. M. S. Pembrey and another on clinical considerations and treatment by Dr. W. Hale White, both of which afford a large amount of valuable information.

The second division of this volume, that devoted to the infections, has also been made the subject of some changes. The article on the General Pathology of Infections has been omitted and will appear in an extended form in the second volume. The articles on Puerperal Septic Disease and on Furuncles and Carbuncles have also been left out, while those on Cholera and Plague will appear in a later volume under Tropical Diseases. The article on Aerotherapeutics has also been transferred from this volume to a later one.

In regard to the remaining articles we have found that they have been brought up to date and are most useful for reference. One which may be specially mentioned is the excellent article on Inflammation by Professor J. G. Adami, which contains the record of a great deal of new work and is one of the most able expositions of the subject with which we are acquainted.

As a whole, the work is one of which the profession of medicine in this country may well be proud and one which, like its predecessor, will be of great value to the investigator and the practitioner who desires to keep himself informed of the advances in medical knowledge and to have the current state of that knowledge conveniently summarised.

Untersuchungs- und Behandlungs-methoden der Kehlkopfkrankheiten. (*Methods of Exploration and Treatment of Diseases of the Larynx.*) By Dr. THEODOR HERYNG. Illustrated. Berlin: Julius Springer. 1905. Pp. 383. Price 12 marks.

Dr. Heryng states in his preface that his object has been to set before the student of laryngology the treatment and technique of laryngeal affections in an exhaustive and yet simple manner, while he has also sought to lay before his fellow specialists those facts and methods which an experience of 32 years has shown to be of real practical value. It is interesting to note that after a trial of all forms of electric illumination in the examination of the larynx Dr. Heryng has returned to the use of the Welsbach incandescent mantle as being, on the whole, the most practical and the cheapest light and that which most clearly resembles good daylight. He gives some useful hints as to its management. He speaks approvingly of autoscopy first described by Kirstein as bringing directly into view the deeper parts of the throat, the larynx, and the trachea by means of a special tongue depressor, the neck being placed so as to bring the opening of the mouth and of the larynx into a direct line. Whilst admitting the advantages of autoscopy in many cases, however, Dr. Heryng agrees with Kirstein that it is an art which requires much practice, and he also admits that many patients complain of the process as being rather distressing. Amongst the very large number of chemical products available for local application Dr. Heryng recommends those only which he himself has found to be useful. He has had a considerable experience of various methods of inhalation and of spraying remedies into the upper air passages, trachea and bronchi, and hence can speak with some authority. The subject matter of the book is treated very fully without being prolix and the work can be recommended as affording a good and practical *résumé* on the matters of which it treats.

Essentials of the Practice of Medicine prepared especially for Students of Medicine. By WILLIAM R. WILLIAMS, A.M., M.D., formerly Instructor in Medicine and Lecturer in Hygiene, Cornell University Medical College; Tutor in Therapeutics, Columbia University, New York. London: Henry Kimpton. 1905. Pp. 460. Price 6s.

THE author of this work states that he aims at presenting no new facts but he wishes to emphasise the more common aspects of various diseases. He simply describes what he terms "the average case" of each particular malady because he apparently believes that this is the way in which to teach the student the practical part of his profession. We cannot agree with Dr. Williams in this respect. The "average case" ought certainly to be impressed upon the student's memory but he will require to know a great deal more than that if he wishes to succeed in his profession. It may be argued that a text-book of this character is simply to prepare a student for his examinations but to be worthy of its name a manual of medicine should have higher aims than this and should be an aid in preparing the future medical practitioner for the actual practice of his profession. Dr. Williams's book certainly cannot replace the larger standard works which a student will be better advised to use, although he may refresh his memory by a reference to its pages shortly before presenting himself for his examination. At the end of each section are arranged a few questions, so that the student can judge for himself whether he has thoroughly understood what he has been reading. He can also from time to time test his memory by referring to these questions and can study those subjects in which he finds his knowledge to be defective. The book is well printed on good paper and the frequent use of heavy type adds to the facility of reference.

LIBRARY TABLE.

The Principles of Bacteriology: a Practical Manual for Students and Physicians. By A. C. ABBOTT, M.D., Professor of Hygiene and Bacteriology and Director of the Laboratory of Hygiene, University of Pennsylvania. Seventh edition. Enlarged and thoroughly revised, with 100 illustrations, of which 24 are coloured. London: H. K. Lewis. 1906. Pp. 689. Price 12s. 6d. net.—The sixth edition of this work published in 1902 was reviewed at some length in our columns and its characteristic features were then pointed out. It is needless therefore to do more than to indicate the alterations or additions which have been made in this edition to bring the subject up to date. The alterations consist chiefly in the omission of certain organisms from the descriptive section and the inclusion of others which have become more important and in the use of a classification and nomenclature more in accordance with modern systematic bacteriology. The principal addition consists in the incorporation of the practical results of importance in preventive medicine. Examples of the first class of change are found in the incorporation of descriptions of the bacillus xerosis and the bacillus paratyphosus, while of additions with a practical bearing may be mentioned various methods of culture of the gonococcus, anti-plague serum and vaccine, anti-tubercle vaccination, standardisation of diphtheria antitoxin, and a more lengthy description of methods employed in the isolation of the bacillus typhosus. The chapter on Infection and Immunity formed an important section of the sixth edition and an attempt has been made in the seventh edition to present the subject with as great comprehensiveness as possible, so as to give some acquaintance with the many-sided relationships which this question has developed as the result of the large amount of work done during recent years. It is scarcely possible within the limits appropriate to a text-book to treat satisfactorily the immense subject of infection and immunity but in this work the student is given a very judicious and well balanced account of the present views on this question. It still remains true, as was said of the last edition, that though possibly more systematic treatises may be found it would be difficult to select a work more stimulating to the intelligent student or one by means of which he could better teach himself bacteriology than this by Professor Abbott.

Introduction to Chemical Analysis. By HUGH C. H. CANDY, B.A., B.Sc., F.I.C., Lecturer on Chemistry in the London Hospital Medical College. London: J. and A. Churchill. 1905. Pp. 114. Price 3s. 6d. net.—Though this book covers old and well-worn tracks the author's method of introducing the subject of chemical analysis to the reader is fresh, and in our opinion this method is the only way which will insure the foundations of the science being well and truly laid, for when a student is taught to observe for himself and to reason for himself the meaning of things the real solid work of education is begun and a sound knowledge of principles as well as of facts is gained. Mr. Candy says in the preface that he has for many years been more or less engaged in the education of students to whom the faculty of accurate and intelligent diagnosis is especially valuable. Exactly what is wanted nowadays is the instilling of this sense of diagnosis into the minds of all students and not the cramming of their brains with so many apparently disjointed facts. That is the aim of Mr. Candy's book in regard to chemical analysis, to explain, as he says, the principles upon which intelligent analysis is based and to make the process a mental rather than a manual one. The examinational system is, of course, calculated to defeat this rational method of teaching, but even when the passing of an examination is the end in view the methods involved can, and ought to be, conducted intelligently and on a reasonably broad basis. Students commencing a course of chemical analysis will find this book to be a real help.

The Laboratory Book of Dairy Analysis. By H. DROOP RICHMOND, F.I.C., Analyst to the Aylesbury Dairy Company, Limited. London: Charles Griffin. 1905. Pp. 90. Price 2s. 6d.—This little book is practically a synopsis of the methods employed for the analysis of milk and milk products which are described in the author's larger work on "Dairy Chemistry." It contains, that is, working directions for the estimation of fat, proteid, and sugar in milk and for the detection of adulterations. Methods are also given for the analysis of cream, condensed milk, butter, and cheese. Mr. Richmond writes with peculiar authority on these questions, having devoted years of work to the examination of milk. The processes recounted, therefore, may be taken to be trustworthy since they must be the outcome of considerable experience. The methods described are for the most part easily carried out but they may contain pitfalls for the operator who has not had the advantage of a skilled training.

The Public Schools Year-Book, 1906. London: Swan Sonnenschein and Co. Pp. 675. Price 2s. 6d.—This is a useful directory of information concerning the public and preparatory schools of the country. The "public" schools included are the 60 large schools connected with the Head masters of Public Schools Conference, no less inclusive or more arbitrary selection being possible. Under each of these schools will be found complete information as to the educational curriculum, the scholarships and exhibitions, the boarding-houses, and the tuition fees, together with a list of the masters. Those private or preparatory schools, we take it, are inserted of which their proprietors have sent the necessary particulars, and here the book will be especially useful to parents who are much more able to get data from which to select the public school than from which to select the private school. We should like to see published in future editions the diet-sheets of the "public" schools and the names of the medical men who either as official medical officers or otherwise can be consulted upon all sanitary points n relation to each school.

The Cambridge Year-Book and Directory, 1906. London: Swan Sonnenschein and Co. Pp. 784. Price 5*s*.—This directory gives the Christian names and surnames, colleges, degrees, and present addresses of all those living graduates of the University concerning whom the editor has been able to obtain the necessary information. We have tested the book carefully and while we admit its obvious utility we doubt whether so high a percentage of correct identification has been obtained as is claimed in the preface, where the editor suggests that all but "something under 5 per cent." are traced. The directory, however, has obvious uses and the editor has a right to expect assistance from Cambridge men both in correcting slips in the names that he has obtained and in furnishing names that have so far escaped entry. Such outside assistance should immediately make the directory a valuable compilation.

New Inventions.

AN AXIS-TRACTION ATTACHMENT FOR ORDINARY OBSTETRIC FORCEPS.

THE accompanying illustrations show an axis-traction forceps made to my design by the Holborn Surgical Instrument Co., Limited, 26, Thavies Inn, London, E.C. It is an ordinary Barnes-Simpson pattern of forceps fitted with a removeable clamp and outside traction rods with handle, the latter having a universal joint. The method of attaching the tractors is simple and no alteration is required in any standard pattern of forceps. All extra parts are loose for cleaning and their total weight is about one and a quarter pounds. They can always be carried in the midwifery bag and provide a method of using the ordinary forceps for axis-traction without the necessity of possessing a special instrument.

AN ADJUSTABLE GREAT COAT FOR WALKING OR DRIVING.

EVERYBODY who has ever worn a great-coat knows that although the opening in front may be closed when the wearer stands up when he sits down there is a gap. When the wearer is driving a horse-drawn vehicle or a motor car this offers every opportunity for draughts to play the legs and the lower part of the abdomen unless the v is protected by a rug, and this, in the case of driving a car, is very much in the way. We have recently inspec great-coat which seems to us to obviate the disa tages of the ordinary great-coat. By means of wh known as a box-pleat the skirt of the coat entirely cove knees and the feet when the wearer is sitting while affo perfect liberty to the legs. When standing up the looks just like an ordinary great-coat. The illust explains the construction of the coat better than any am of description. It is made by Messrs. John Robeson Co., 196, Aldersgate-street, London, E.C., and seems to be a praiseworthy invention.

Showing coat arranged for driving.

LONDON: SATURDAY, APRIL 7, 1906.

The Workmen's Compensation Bill.

IN the House of Commons on March 26th the Home Secretary introduced a Bill "to consolidate and amend the law with respect to compensation to workmen for injuries suffered in the course of their employment." Mr. GLADSTONE'S proposals on the whole met with a favourable reception from both sides of the House and the Bill was read for the first time. Briefly, the new Bill seeks to extend the Workmen's Compensation Acts of 1897 and 1900 to every class of labour. The expression "workman," however, is to include every person not being a member of a police force, a clerk, a shop assistant, an outworker, a domestic servant, or a member of the employer's family dwelling in his house who has entered into, or works under, a contract of service or apprenticeship with an employer. Not only, therefore, are workmen employed in workshops to be brought under the operation of the Act but also those employed in the transport service, as well as fishermen, postmen, and seamen. Doubtless the promoters of the Bill have their reasons for excluding clerks, shop assistants, and domestic servants from the provision of the Act, but by what validity of reasoning these persons should not share the same advantages which the Act seeks to offer to "workmen" we fail to see. All three classes of labour—the clerk, the shop assistant, and the domestic servant—represent a very large and deserving section of the labouring community, and, moreover, their occupation, as experience has shown, is not unattended with risk. Further, it is difficult to understand why the Act should not apply in any case where the employer proves that the number of workmen employed by him at the time of accident did not exceed five unless the accident was attributable to the use by the employer of machinery driven by steam, water, or other power, or unless the workman at the time of the accident was employed in the care or management of horses or in mining, quarrying, or building operations, or in laying or repairing any electric line or work. We imagine that although the limit of five will not be made to apply to cases where machinery is used, there might be conceivably cases in which even the workmen engaged by the small employer are exposed to accident, although the nature of the work may not be such as to involve the use of dangerous machinery. The Bill, however, as Mr. GLADSTONE was careful to state, was not, and could not, be final, and when the Government had seen how it worked fresh proposals might be made to make up proved deficiencies, to extend its operations to other classes, and to get rid of limitations.

One of the most important extensions in the Act is the proposed application of its provisions to industrial diseases. The third schedule gives a list of these diseases as follows: anthrax (derived from wool combing or sorting and the handling of hides and skins), lead poisoning (arising from any process involving the use of lead compounds), mercury poisoning (originating from the use of mercury compounds), phosphorus poisoning, arsenic poisoning, and ankylostomiasis (mining). We have for several years insisted, at all events, in the case of lead poisoning in the potteries, that the manufacturers should be compelled to compensate their workmen who through no fault of their own are exposed to the poisonous action of raw lead compounds and who develop "plumbism." We suggested also that those potters who adopted leadless glazes or at least harmless lead compounds (the so-called "frits") should be exempt from the requirements of the Act. Industrial poisoning, it is obvious, cannot be placed on the same footing as an accident. The date of the latter can be fixed with certainty but it might be difficult to say when metallic poisoning was contracted, and it might even be possible for an operative to contract the disease under the roof of one employer and to develop it under that of another. Either employer, knowing these facts, would be ready to deny responsibility and it would not be easy to determine in every case on whom the penalty of compensation should fall. The onus of proof will be thrown on a medical referee appointed by the State, for Clause 11 states that the Secretary of State may appoint such legally qualified medical practitioners to be medical referees for the purposes of the Act as he may determine, and the remuneration of, and other expenses incurred by, medical referees shall, subject to regulations made by the Treasury, be paid out of moneys provided by Parliament. Remuneration is to come from the same source when a medical man is summoned to sit with the judge of a county court as a referee. On a workman giving notice of an accident he shall, if required by his employer, submit himself for examination by a duly qualified medical practitioner provided and paid by the employer. In the event of a disagreement arising between the employer and the workman as to the fitness for work of the latter the matter is to be taken to the State medical referee. If the workman refuses to submit himself for this purpose it is proposed to suspend his right to compensation until such examination has taken place.

One other point calls for comment and that is with regard to the payment of compensation. Under the existing law an application for compensation cannot be made until a fortnight has elapsed from the time of the accident. It is now proposed to reduce this interval by at least one week, so that deserving sufferers may not be deprived of the first week's payment of compensation. On the other hand, this step will greatly increase the cost of compensation, and there are a good many accidents which involve less than a fortnight's illness. Moreover, if by reducing the period which must elapse after an accident before compensation can be claimed fraud and malingering are encouraged, it is evident that no concession of shorter time ought to be given. In the House of Commons on Wednesday a discussion on the second reading of the Bill took place, when Mr. GLADSTONE stated that if the House desired the proposals of the Bill could be extended, while some scheme of compulsory insurance, he thought, would ultimately be necessary.

The Education of Crippled and Mentally Defective Children.

WE have received a copy of a report made to the Manchester education committee by Dr. HENRY ASHBY on the special schools for the mentally and physically defective children of that city. This annual report, the third of a series, though only of six pages is of considerable interest and contains valuable information of the methods adopted and the results obtained. There are three special day schools for mentally defective children, affording accommodation for 218 pupils. During the year 1905 263 children attended these schools and Dr. ASHBY is able to report that the school work has been conducted with great enthusiasm and interest by the teachers and that a marked improvement in attainments and conduct has taken place as regards the children. It is gratifying, also, to find that the parents are beginning to recognise the useful character of these schools and that there have been very few instances of their refusing to allow their children to attend or withdrawing them; indeed, in some instances the parents have voluntarily brought their children for examination and admission when they were conscious that there was some defect in the capacity for learning. Seven of the children were transferred from these day schools to the Sandlebridge boarding schools belonging to the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded, as being more suited for a residential school. Seven epileptics were transferred to the David Lewis Epileptic Colony owing to the severity or frequency of their fits. Seven cases were discharged as too feeble-minded to benefit much at a day school.

During the year 13 children who were 14 years of age were allowed to leave at the wish of their parents with the object of trying to obtain work; six of these were boys and seven were girls. Of these six boys three are working and doing well; one of them is earning 10*s.* a week, with good prospects, while the other two are earning 5*s.* or 6*s.* a week; the remaining three have failed as yet to secure permanent work. Of the seven girls four are working and doing well, two cannot be traced, and one has left the district. Of the four who are at work one is cap making, one is doing needlework, and two are engaged in housework at home. During the present year Dr. ASHBY anticipates that from 20 to 30 children will be leaving school and he is very anxious to trace their careers and their future prospects. He is of opinion that it is futile to admit to these schools the lower class of defectives or border-land imbeciles, since although the training and good example are beneficial yet they learn but little from school books and as their powers of retention are so feeble no permanent results are achieved. On the other hand, he regards it as probable that a certain proportion of those passing through the schools will be eventually able to earn their own living, especially if they are sent to the special schools when they are seven years of age and if simple handicraft trades such as basket-making, caning chairs, and mat- and toy-making are taught to them by practical teachers. Some of them, however, from lack of initiative and intelligence will degenerate after leaving and these are more fitted for colony life where the conditions of example and discipline similar to those of the schools are maintained.

In regard to the instruction of crippled or physically defective children prevented from attending the ordinary schools the Manchester education committee has set an excellent example to other educational authorities. During the year 1905 a residential school for crippled children was opened at Swinton House with accommodation for 30 children. A special and noteworthy feature of this school is that it works in conjunction with the children's hospitals and continues the treatment while providing some education. In the few months during which this school has been at work 34 children were admitted, all suffering from some chronic disease, paralysis, or deformity which was of such a degree as to prevent their attendance at a day school. For the most part, though of quite average mental powers, they were very backward and in some instances had received no school instruction whatever. Of these 34 children, 14 had spinal deformity, ten deformity from disease of the hip, five had severe deformities due to rickets, three were paralysed, and two had old disease of the knee. Six of them were temporarily transferred to the Children's Hospital for operation, the parents' consent having first been obtained. Many of the children were confined to bed, while others were enabled to get about on crutches. In nearly all cases they improved notably in health and made good progress in their school work. We understand that this school is the first of its kind in this country and the Manchester education committee is to be congratulated on its scheme for dealing with a difficult problem and on its wisdom in securing the coöperation of the medical man and the school teacher to lessen the disabilities inflicted on these children by heredity, disease, or misfortune. In the past many of these defectives, from lack of the special care now provided, instead of becoming useful and productive members of society as they are capable of doing, have been chargeable to their relatives or to the community for their support. The attempt to ameliorate their lot deserves the sympathy of all. Dr. ASHBY's report is a most suggestive and thoughtful pamphlet and deserves careful and attentive study by educational authorities elsewhere.

◆

Our Military Medical Service in Peace and War.

AN interesting and instructive debate took place in the House of Commons recently on the Army Estimates in connexion with the vote of £490,000 for the Army Medical Establishment and Service. Several Members took part in the debate, and it may be hoped that the feeling is becoming more general in Parliament that the condition of the Army Medical Service is an affair of national importance. The debate elicited a good speech from Mr. BURDETT-COUTTS and an important statement from the present Secretary of State for War. Like the far greater problem of how to guard against our unpreparedness for war generally and how to supply the regular army of the future with an adequate reserve—the need of which was perhaps the supreme

Our Military Medical Service in Peace and War.

AN interesting and instructive debate took place in the House of Commons recently on the Army Estimates in connexion with the vote of £490,000 for the Army Medical Establishment and Service. Several Members took part in the debate, and it may be hoped that the feeling is becoming more general in Parliament that the condition of the Army Medical Service is an affair of national importance. The debate elicited a good speech from Mr. BURDETT-COUTTS and an important statement from the present Secretary of State for War. Like the far greater problem of how to guard against our unpreparedness for war generally and how to supply the regular army of the future with an adequate reserve—the need of which was perhaps the supreme investigation. For keeping bodies for identification and further observation it is an excellent procedure. The drawback to it is that though practicable it is not very expedient where transportation over long distances is required. There are many preservatives—e.g., formalin—very efficacious in their action which at the same time are little likely to be employed as poisons. We trust that the action taken by the American Medico-Legal Society will lead to legislation which will put an end to a practice by which the criminal law may be violated with comparative impunity.

THE MEDICAL REGISTER FOR 1906.

IN THE LANCET of March 31st we noted the appearance of the Medical Register and made various comments thereupon. Amongst other points we noted that we had checked the first 25 names in the Obituary List of the current Medical Directory and we said: "Of these 25 one is still on the Medical Register." We find that in this respect we have unwittingly done an injustice to those responsible for the accuracy of the official list of the profession which we are anxious to repair. Last year there were two practitioners, doubtless a father and son, bearing identical names. The father is now dead but the son's name remains on the Register and this identity of names led us into an error for which we desire to express our regret.

THE SECOND INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

ANYTHING which tends to bring nations together in friendly conference must receive the support of all those who wish that war could be no more, and the International Congresses on School Hygiene, though not directly organised with the object of establishing peace among the nations, must of necessity tend towards that desirable end, though their immediate purpose is to promote hygienic conditions in schools. On March 30th, in the Jehanghir Hall of the University of London, South Kensington, W., His Grace the Duke of Northumberland presided at a preliminary meeting to arrange the details of the Second International Congress on School Hygiene to be held in London from August 5th to 10th, 1907, under the presidency of Sir Lauder Brunton. It will be remembered that the first Congress was held in Nuremberg in Easter week, 1904, when a large number of representatives of continental societies interested in education attended. The French people, whose interest in school hygiene is very great, wished the second Congress to be held in Paris, but they have magnanimously given way to the wishes of England and, as Sir Lauder Brunton pointed out at the meeting on March 30th, have signified their determination to do all in their power to make the Congress in London a complete success. With the help of our neighbours across the Channel and the promised cordial coöperation of other countries there can be no doubt, as Sir Lauder Brunton said, that the forthcoming Congress will be one of the largest and most important ever held in London. The first motion, which was carried unanimously after being proposed by the Right Hon. Lord Reay and seconded by Canon Lyttelton, head-master of Eton College, stated:—

> That in view of the importance of school hygiene in developing a strong and vigorous race, the necessity for scientific methods being followed in the training of the young, and for hygienic surroundings being supplied in order to promote the health of the children during school life, this meeting, consisting of representatives of educational authorities, medical men, teachers, and others, is unanimously of opinion that it is desirable to hold the Second International Congress in London in August, 1907, to which representatives from India and the colonies should be invited, in addition to representatives from other countries.

Canon Lyttelton, in the course of his remarks, referred to the difficulties which head-masters of secondary schools had in dealing with hygiene in schools owing partly to lack of knowledge on the part of the public and partly to the need of an organisation to which the head-masters could appeal as an authority. On the motion of the chairman it was decided to ask His Majesty the King to extend his Royal patronage to the Congress. Knowing, as everyone does, the interest which His Majesty takes in all matters concerning the welfare of his subjects there is little doubt that he will graciously respond to the wishes of the meeting. An important motion was proposed by Sir Richard Martin, the treasurer of the Congress, namely:—

> That in view of the large expenditure involved in organising an international meeting of this character this meeting is of opinion that steps should at once be taken to obtain subscriptions and to open a Congress Fund, and that an appeal should be issued to all those interested to enable the committee to make the Congress not only a success, but worthy of the country whose hospitality the meeting will enjoy.

The estimated amount for expenses is £4000, comparatively a small sum to pay for the undoubted benefits which must result from the holding of the Congress, and we hope that a still larger sum than this may be subscribed in order that there may be a surplus with which to extend the good work. Among the other speakers who supported the movement were Sir John Cockburn, K.C.M.G., Sir William Broadbent, Sir Shirley F. Murphy, and Sir Edward Brabrook, chairman of the organising committee. The offices of the forthcoming Congress are at 72, Margaret-street, W. It may be mentioned that every person interested in promoting the hygiene of school life is eligible for membership upon furnishing the local committee with an exact statement of his or her name, position, title, and address, and paying the subscription of one guinea, or five dollars. A card of membership will be issued entitling the holder to attend all meetings, discussions, and entertainments, to receive the literature and proceedings, and to enjoy all other privileges of the Congress.

EPITHELIOMA DEVELOPING ON AN X RAY SCAR IN A CASE OF LUPUS VULGARIS.

IT is a curious fact that the x rays, though curative in some forms of epithelioma, may be the exciting cause of this disease. In the *British Journal of Dermatology* for March Dr. J. M. H. MacLeod emphasises the necessity of avoiding this danger in the treatment of lupus vulgaris by taking care not to bring about a severe reaction with the production of a telangiectatic scar. He relates the following case. A woman, aged 24 years, had suffered from lupus vulgaris of the face since childhood. She had been treated surgically several times and had subsequently undergone a prolonged course of treatment with the x rays. In June, 1902, she came under his care with a large cicatrix in the right lower half of the face and extending down to the root of the neck. This was evidently the result of severe x-ray dermatitis. It was smooth and pale in the centre but showed a close network of dilated capillaries towards the periphery. Around it was an areola of pigmentation. So far as the destruction of the lupus was concerned the treatment was fairly satisfactory but the disfigurement was great. There were, however, a few foci of active lupus outside the area of scar. These were treated with the Finsen-Reyn lamp. In October the improvement in these lesions was so marked that no definite disease could be detected. In January, 1904, several foci outside the area of scar became active and the Finsen treatment was repeated. At this time the x-ray scar remained sound. In the beginning of 1905 there was a small reddish-brown patch in the centre of the scar at the level where the collar of the dress rubbed against the neck. This patch was of about the size of a sixpence, slightly raised, indurated, and covered by scaly thickened epidermis which was almost verrucose. On pressing the blood out with a diascope there was evidence of underlying granulomatous infiltration. A few exposures is that the formation of an army medical reserve is imperative, and we believe that the country will not find the task of its creation difficult if the medical profession feels that it can rely upon an intelligent attitude on the part of the military authorities. But this attitude is absolutely necessary.

Annotations.

"Ne quid nimis."

THE METROPOLITAN ASYLUMS BOARD AND SANATORIUMS FOR CONSUMPTION.

IN a leading article in THE LANCET of Feb. 24th last, p. 534, we discussed a proposal made by Sir William Broadbent that the Metropolitan Asylums Board should "constitute itself" the "tuberculosis authority" for the metropolis and we pointed out that, desirable as certain aspects of the proposal might possibly prove from a purely humanitarian standpoint, there were obvious drawbacks to the scheme as a whole which rendered it administratively impracticable and inexpedient. It was suggested, in fact, that what would in effect have been a new sanitary authority should be created in the metropolis to deal with one disease alone, and this notwithstanding the fact that the borough councils, or rather their predecessors, were created largely for the purpose of controlling, except in so far as actual isolation is concerned, the infectious diseases occurring in their districts We are not, therefore, altogether surprised to find that the Local Government Board, to which the question of the provision of sanatoriums was referred by the Asylums Board, after having devoted much careful consideration to the subject, has replied that the information at present before it does not appear to afford sufficient justification for the very heavy outlay which would be involved in the proposal. The Board also inclosed with its reply a copy of a communication which Sir William Broadbent has addressed to Mr. Burns in which he practically withdraws the specific proposal which he had outlined and which, we gather, was made under some misapprehension of existing sanitary administration in the metropolis. Sir William Broadbent is now of opinion that the Metropolitan Asylums Board is too extensively associated with Poor-law administration to act as a tuberculosis authority for non-pauper cases and he was, he adds, misled by the fact that cases of infectious disease are sent to the hospitals of the Asylums Board whether or not such cases belong to the pauper classes and he was not, he states, aware that the Metropolitan Asylums Board, being elected by the guardians, is unable to exercise the coördinating authority which he had in view. As we have already expressed our views upon the subject we do not propose to discuss the matter at any length at the present moment. It is, however, clear to us that the expenditure involved would have ultimately become enormous, seeing that it would have led eventually to the general provision both of sanatoriums and of homes for advanced cases as well as to a material addition to the sanitary administration in the metropolis. We think, therefore, that the Board has done wisely in waiting for further information as to the many aspects of the problem before officially sanctioning an experiment with a population of some 5,000,000 people, more especially in face of the criticisms which are being made as to the influence of hospitals in reducing the prevalence of the more highly infectious diseases such as scarlet fever and diphtheria. If, as seems possible, the London public is in the mood to furnish substantial funds for the purpose of endeavouring to hasten the decline in the death-rate from tuberculosis it is desirable that the money should be spent on a well-organised scheme which will be likely to yield the best results.

EMBALMING AND POISONING.

IN his inaugural address before the American Medico-Legal Society on Jan. 17th the President, Dr. Clark Bell, LL.D., directed the attention of members to the legal prevention of the use of poisons in the embalming fluid by undertakers and others. The subject is of the highest importance, since it is well known that criminals have employed agents to inject arsenical and other poisonous solutions into the cavities of the cadaver with a view to prevent the detection of their crime. In some countries restriction has been made relative to the use of arsenic as an embalming medium and many years ago it was forbidden in France. As pointed out by Dr. Bell, there is no certain method by which "arsenic administered by the mouth or rectum which produced death can be detected or discriminated from the arsenic with which the abdominal cavity had been filled contained in the embalming fluid of the undertaker—which had been absorbed by the dead body by imbibition." We shall watch with interest the result of the deliberations of the committee of investigation proposed by the American Medico-Legal Society. The statement is doubtless correct that "it is now demonstrated that a perfectly sure, safe, and reliable embalming fluid can be made without the use of arsenic or any poison or ingredient dangerous to human life." As Dr. Bell observed, there is no reason to believe that the Egyptians relied on poisons in their best work or that they used poisons. It may not be out of place here to give a short historical sketch of the processes of embalming employed at different epochs. The preservation of dead bodies in ancient times was practised by the peoples of both the old and the new world, by the Persians and the Peruvians for example. The latter appeared to have relied on the preservative action of cold, dry, and rarefied air, for they placed the bodies of the Incas to desiccate on the mountains. The Egyptians alone of the ancients employed embalming as a ritual due to the dead. Even with them we can follow the development of the usage, for the sarcophagi of the earliest dynasties did not contain mummies, though skeletons found in some of them had a bituminous odour and were brown in colour, suggesting a primitive attempt at embalming. Herodotus describes three grades of embalming, varying in nature and procedure according to the tariff. In the first or highest class the brain was removed through an opening made in the skull by crushing the ethmoid bone. The organs of the abdomen and thorax after removal were washed with palm wine and treated with aromatics. The cavites of the abdomen and the thorax were filled with cassia, myrrh, and so on. The body was put in natrum—subcarbonate of sodium—for from about one to two months and finally it was swathed with bandages charged with gum. Like other arts, embalming was lost in the dark ages. It was at the commencement of the nineteenth century that chemicals were first employed by Chaussier who recommended that the surface of the body and the inner walls of the great cavities should be treated with a solution of corrosive sublimate. In 1834 Gannal brought to the notice of the Academy of Medicine of Paris his plan of injecting a solution of salt, saltpetre, and alum into the arteries, and so doing away with the necessity of removing the internal organs. Arsenic, zinc chloride, and mercuric chloride have been the minerals most commonly employed for the preservation of dead bodies. By freezing the cadaver can be kept free from putrefaction for an unlimited period without using substances that might by their chemical properties prevent or interfere with toxicological the right eye there was some atrophy of the optic nerve with but little change in the vessels. In the left eye there was some atrophy of the optic nerve with veiling of its upper and inner margin. The veins were extremely tortuous. Further examination showed that the right sixth nerve was completely paralysed. There was slight paralysis of the right seventh nerve; the forehead was not wrinkled as much or the angle of the mouth drawn up as well on the right side as on the left. The tongue deviated a little to the right and showed fibrillary tremor on both sides and atrophy on the right. The soft palate was slightly but distinctly weak on the right side. The left vocal cord was completely immobile and fixed in the middle line; the right was active but showed weakness in sustained tension. Smell and taste were normal. Thus there were on the right side paralysis or paresis of almost all the cranial nerves and on the left side partial paralysis of the third nerve. The diagnosis of thrombosis of the cavernous sinus best explained the ocular symptoms. Sir William Macewen has shown that in more than half the cases of thrombosis of the cavernous sinus the process extends to the other side by the circular sinus. He considers that this extension serves to differentiate between disease of the cavernous sinus and diseases within the orbit. In the case now reported the evidence of this extension was involvement of the motor nerves of the left eye. The paralysis of the ocular nerves was evidently due to the pressure exerted on them by a thrombus in the cavernous sinus. Extension of the thrombosis backwards into the superior and inferior petrosal sinuses would explain the other paralyses. The superior petrosal sinus on its way to join the lateral sinus crosses the fifth and seventh nerves. The inferior petrosal sinus as it crosses the anterior compartment of the jugular foramen separates the glosso-pharyngeal from the spinal accessory nerves. Perhaps the disturbance of the circulation caused by thrombosis of the inferior petrosal sinus affected the nuclei of the nerves. The increase of the ocular symptoms at the menstrual periods can be explained by the general disturbance of the circulation which is produced by menstruation.

THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.

A FESTIVAL dinner in connexion with the above hospital was held in the Whitehall Rooms, Hôtel Métropole, London, on April 3rd. Field-Marshal the Right Hon Earl Roberts presided. A large number of ladies and gentlemen attended and amongst those present were the Lord Chief Justice of England (the Right Hon. Lord Alverstone) Count Metaxas, and the President of the Royal College of Physicians of London (Sir Richard Douglas Powell). The loyal toasts having been duly honoured, Earl Roberts proposed "Prosperity to the Hospital." He said that he remembered hospitals before the great and beneficent discovery of Lord Lister and he recollected the sufferings which the patients endured before the introduction of the antiseptic system. He then gave a brief account of the history of the hospital and the work that had been accomplished. Established in 1867, the hospital possessed accommodation for 150 patients. It comprised 11 blocks and each patient occupied a separate bedroom. Upwards of 22,000 in-patients had already received the benefits of the institution, many of whom had been enabled to resume their occupations after leaving the hospital. The institution being out of London derived no assistance from King Edward's Hospital Fund. A festival dinner in aid of the hospital had not been held for some years and he hoped the results that night would be as satisfactory as on the occasion ten years ago when Lord Alverstone was in the chair. The next toast was that of "The Board of Management and the Medical Staff," given by Sir Richard Douglas Powell, who said that the members of the board must have something of the Mark Tapley element about them with just a dash of Mr. Micawber, for they dealt with an institution having an income of £11,000 and an expenditure of £14,000, yet did not "wear a worried look." They managed their funds most carefully but always looked for a legacy or a big donation "to turn up." The institution of the aseptic method of treating pulmonary tuberculosis had proved most encouraging. Mr. P. B. Burgoyne (chairman of the board) and Dr. R. Robertson (physician to the hospital) replied. "The Health of the Chairman" was proposed by Lord Alverstone and Earl Roberts, in reply, made the welcome announcement that £2110 had been collected as the result of the dinner and that His Majesty the King had given £50 towards the funds of the hospital. Mr G. T. Powell (deputy chairman of the board) proposed the toast of "The Visitors, the Ladies, and the Artistes," and Mr. G. C. Milo, Mr. Alan Burgoyne, and Chevalier Wilhelm Ganz responded.

INTERNATIONAL MEDICAL ASSOCIATION FOR THE SUPPRESSION OF WAR.

THE International Medical Association for the Suppression of War was founded a year ago and the annual general meeting was held on March 21st at the headquarters of the association, 25, Rue des Mathurins, Paris. Dr. J. A. Rivière, the President, was in the chair and delivered an address. He said that the world was still to a great extent dominated by views identical with those held by the ancients, and although Mars, the god of war, was no longer an object of public worship yet the ideals associated with his name were firmly established in the minds of the people of all nations. What other explanation was there of the fact that women, whose hearts were full of tenderness and pity, had done nothing to bring about the abolition of war? He had no doubt as to the final triumph of reason and good sense. The breath of truth was as contagious as that of error. In conclusion, he said that international disputes brought before a duly constituted tribunal, the proceedings of which were open, were, in fact, adjudicated on by public opinion. A large number of medical men of many nationalities were present at the meeting and several motions were adopted in accordance with the views enunciated in the president's address.

THE ANTISEPTIC VALUE OF HETRALINE.

WE have received a copy of a dissertation for the degree of Doctor of Medicine by Dr. Ramon Fernandez de Caleya y del Amo, detailing some observations on the antiseptic value of hetraline and comparing it with that of urotropine in septic conditions of the urinary passages. The writer points out that since it has been demonstrated that in the majority of cases cystitis and pyelitis are caused by pathogenic organisms search has been made for antiseptics the action of which, whether by local application or by internal administration, would be sufficiently powerful to destroy the bacteria without damaging the tissues. He mentions urotropine as being the most satisfactory hitherto employed and then proceeds to give his experience of another preparation—hetraline. The chemical term for this substance is dioxybenzoylhexamethylenetetramine; it crystallises in needles which are soluble in cold water (1 in 14) and in alcohol but far more readily in hot water (1 in 4). It has a sweet, agreeable taste. The conclusion arrived at is that the preparation is a good urinary disinfectant, as powerful as urotropine and occasionally superior to it. Hetraline has the advantage of causing no irritation to the tissues, at any rate, in the doses used by the author of the dissertation. The minimum daily quantity is four doses of 0·5 gramme; smaller doses do not yield good results. The bacteria are not destroyed but microscopical examination showed that the organisms had become misshapen and stained badly with methylene blue.

to the rays reduced the granuloma but made no impression on the thickened epidermis. The patient then disappeared for several months. She returned in August with recurrence of the granuloma and the thickening of the epidermis more marked. Several exposures were given but as there was no marked benefit they were discontinued lest they should prove harmful by irritating the epidermis and boric ointment was applied. The patch steadily enlarged, its borders became more raised, and a superficial ulcer formed in the centre from which oozed a sero-sanguineous discharge. In October the patch had increased to the size of a shilling and the margins were so hard that free excision was performed. The wound was healed by the middle of December. Microscopic examination showed for about a quarter of an inch beyond the active growth the characters of a burn from the x rays. In the centre was a rapidly spreading squamous epithelioma with cell-nests. Surrounding the epitheliomatous processes was a dense cellular infiltration consisting chiefly of plasma cells and fibroblasts which was thought to be of tuberculous origin. The development of epithelioma in old lupus vulgaris, though well known, is rare. Its development on an x ray scar which has replaced lupus appears to be not infrequent. Mendes da Costa has recorded seven cases in 72 so treated. Such cases show the necessity of avoiding a severe reaction which is likely to occur in tuberculous tissue.

THE GERM-DESTROYING PROPERTIES OF TOBACCO SMOKE.

IT has often been confidently stated that tobacco smoke is a powerful germicide but so far this property has not been assigned to any one particular constituent of the smoke. The composition of tobacco smoke is, of course, complex but everybody knows that tarry oils are a principal constituent and certainly many oils are powerfully antiseptic. Nicotine, again, is a strong disinfectant but the quantity of this poison in tobacco smoke is minute, if, indeed, it is present at all. At least, in a number of chemical analyses of tobacco smoke made at different times it was difficult to declare with absolute certainty that nicotine was an important constituent. The oily matter which accumulates in a tobacco pipe is decidedly poisonous but it does not contain any appreciable quantity of nicotine, the chief constituent being the very poisonous oil pyridine. Tobacco smoke contains a decided quantity of the very poisonous gas carbon monoxide which has been used for preserving purposes and which therefore must possess germicidal properties. Some simple experiments which we have recently made would seem to confirm the observation that one of the principal constituents accounting for the germicidal properties of tobacco smoke is the powerful antiseptic formaldehyde. The amount present is more than just appreciable, for if water through which a few puffs of tobacco smoke have been passed is tested for formaldehyde the result is strikingly positive. The quantity of formaldehyde in tobacco smoke would appear to depend on the quality and kind of tobacco smoked. Thus the cigar appears to yield more formaldehyde than the pipe and the pipe more than the cigarette. Possibly the peculiarly irritating property of the smoke issuing from the glowing end of a cigarette or cigar or from the bowl of a pipe is due to formaldehyde. It has more than once been stated that tobacco smokers enjoy an immunity from certain diseases and the frequent presence of a powerful antiseptic in the mouth, nasal passages, and sometimes the lungs (as in the case of those who foolishly inhale tobacco smoke), would to some extent justify the statement. When it is considered that in the nose a vast number of microbes are hourly deposited it is conceivable that these may be effectively destroyed by the frequent passage of tobacco smoke through that organ. In the same way the organisms exposed to tobacco smoke in the mouth would succumb. Formaldehyde is one of the most powerful disinfectants we possess, 1 part in 10,000 parts of water serving to destroy all microbes, while such a dilute solution has practically no poisonous action on the human organism. All the same, it is most undesirable that this fact should stimulate the practice of smoking tobacco to absurd excess, for tobacco poisoning is a greater reality than many persons think, and to employ tobacco in abusive quantities for the sake of destroying microbes might amount possibly to killing the seeds of one disease only to contract another.

THE FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE, LISBON, 1906.

THE London, Brighton, and South Coast Railway Company gives notice that it is prepared to issue return tickets from London to Irun to members of the International Congress of Medicine and their wives and children. The tickets will be issued until April 19th at the Victoria and London Bridge stations of the London, Brighton, and South Coast Railway, the only formality necessary being the presentation of the *carte d'identité*. The tickets are available for 60 days *viâ* Dieppe, Paris, and Bordeaux. The return fares from London to Irun are £5 15s *5d.* first class and £4 1s. second class.

THROMBOSIS OF THE CAVERNOUS SINUS WITH PARALYSIS OF THE CRANIAL NERVES.

IN the *American Journal of the Medical Sciences* for February Dr. W. Zentmayer and Dr. T. H. Weisenburg have published the following remarkable case. A woman, aged 34 years, came under observation with the following history. In childhood she had fairly good health. Menstruation began at the age of 14 years and after two periods of scanty flow ceased for two years. After that it was regular. A short time before the beginning of menstruation the right eye became inflamed and there were some ptosis and proptosis. The inflammation subsided somewhat but at every succeeding period there was a sense of discomfort and fulness in the right eye and later also in the left. The proptosis and ptosis on the right side gradually increased and were most pronounced at the menstrual periods. The patient married at the age of 24 years. Four years later she noticed at the time of a menstrual period that the right eye was more painful and inflamed than ever before, that the proptosis and ptosis were more marked, and that these symptoms, instead of subsiding after the menstrual flow, became, if anything, more pronounced. Later it was found that these ocular symptoms were the first signs of pregnancy. As the pregnancy advanced all the ocular symptoms increased. Twins were born after a difficult labour. The proptosis and ptosis further increased, the latter becoming complete. At each menstrual period the ocular symptoms continued to augment. When the patient came under observation she complained much of headache. There was marked proptosis on the right side, but the globe could be partially replaced by firm pressure. The right third, fourth, and sixth nerves were completely paralysed. Ptosis was complete, but owing to the proptosis there remained a narrow palpebral fissure. The palpebral veins were congested. The pupil was four millimetres in diameter and did not respond to direct or consensual light stimulus. The lids, the conjunctiva, and the cornea were anæsthetic and there was a large corneal opacity. Vision equalled the counting of fingers at one-sixth of a metre. On the left side there were slight limitation of the inward movement of the eyeball and weak nystagmoid action of all the extra-ocular muscles. The pupil measured four millimetres and did not react to direct or consensual light stimulus. Vision equalled $\frac{5}{10}$. In suffering from diseases of the chest. Those patients who are unable to walk to the clinic will be visited by a physician and by a nurse if necessary. The above intentions are excellent and we wish the promoters of the scheme every success. Full details are not given, however, in the leaflet, but if we are correct in assuming that only one physician is to attend at the clinic for one hour daily but little good can result. The attendance of at least two physicians for three hours or longer daily would be required in *order to see the number* of patients likely to attend. Doubtless, however, the promoters desire to commence on a small scale, enlarging their labours as funds will permit. The supervision of the treatment in the patients' own homes by means of a large committee of competent persons is being extensively tried in France and elsewhere and most valuable results may be expected. We trust that good results will follow the proposed "clinic" in Philadelphia.

THE SIXTH INTERNATIONAL CONGRESS OF CRIMINAL ANTHROPOLOGY.

"WHAT is genius but organisation?" said Mr. G. H. Lewes. "What is crime but the product of vitiated organisation, congenital or acquired?" say Lombroso and his school. The positive affirmation implied in this latter question is the keynote (writes an Italian correspondent) of the new science of criminal anthropology which at intervals of three years holds its international congress, this time at Turin from April 28th to May 3rd. Sixth in the series, the Congress about to meet has set itself an unusually attractive agenda paper to be worked through by such well-known experts as Max Nordau, Richet, von Hamel, Tamburini, Morselli, and the "bon juge" Magnaud, under the presidency of the ex-Minister of Public Instruction Bianchi and with the intervention of Lombroso himself. Its "inauguration" will take place in the Aula Magna of the University and thereafter its sittings will be held in the Istituto di Anatomia Normale, spacious enough to accommodate the "congressisti" representing the leading nationalities or States of the two hemispheres. The first proceeding after the inaugural address will be the presentation of a testimonial to Cesare Lombroso, on the occasion of his "giubileo scientifico," which also coincides with his nomination as ordinary professor of criminal anthropology in the University of Turin. The testimonial will take the form of a "targa (shield) artistica e simbolica,' the work of Bistolfi, a gold medal also designed by the same artist, and an illuminated album containing the signatures of the most eminent votaries of the science of which Lombroso may be called the "hero and eponymus." This ceremony concluded, the Congress will proceed to business and at the close of each day there will be entertainments of one form or another organised by the Municipio, the Circolo degli Artisti, and the *Accademia di Medicina*, in addition to which Professor Lombroso will receive the "congressisti" at a "serata d'onore" and the "characteristic" Borgo Medioevale will offer the hospitality for which it is noted. Before dispersing the "congressisti" will be conducted on an "escursione artistica" through the Val d'Aosta by the historian of Roma Antiqua, Signor Guglielmo Ferrero, who will give apposite explanations of the celebrated antiquities of the locality. *Turin, indeed*, is making every effort to insure the success of the Congress—the first international meeting which she has held since the partial destruction by fire of her magnificent library—if only to show her gratitude for the assistance she received towards making good the losses she then sustained—assistance rendered cordially and effectively by sister seats of learning throughout Europe—conspicuous among these being the Universities of Oxford and Cambridge. *It may be added* that all the information required by intending participants in the Congress may be obtained on applying to the Secretary at the Istituto di Medicina Legale of the Università di Torino, No. 26, Via Michelangelo.

THE EXPERIMENTAL PROPHYLAXIS OF SYPHILIS.

SOME experiments recently described in the *Annales* of the Pasteur Institute are of interest in connexion with the annotation on the Prevention and Early Treatment of Syphilis which was published in THE LANCET of March 17th, p. 775. Having inoculated some monkeys with syphilitic virus, M. Metchnikoff and M. Roux applied friction with a mercurial unguent to the inoculation incisions one hour after they had been made. The subjects remained free from the disease and were subsequently re-inoculated with some of the same virus successfully, whereas the controlling monkeys which had not been subjected to the mercurial inunction in due course developed unmistakable signs of constitutional syphilis. In some cases a solution of corrosive sublimate was employed instead of the unguent but it proved useless as a preventive of secondary symptoms. In 1904 a young member of the medical profession, Dr. Bonnette, wrote an inaugural thesis on the "Utility of Mercurial Unguents in the Prophylaxis of Syphilis." In the first place, he said, grease reduces friction to a minimum. Secondly, greasy substances act as insulators and are extremely tenacious. A finger and thumb, previously greased, may be pressed together as hard as possible but still a thin greasy coating will remain on the digits, which will present a shiny appearance, leave marks on paper or linen, and resist the lodgment of moisture if they are plunged into water. Thirdly, when mercury is incorporated with an unguent applied to an epithelial surface an antiseptic layer is thereby deposited which will prevent microbian invasion by reason of its viscosity and causticity. Finally, although constitutional contamination may take place rapidly there is always an interval of quiescence; the poison does not penetrate instantaneously. As long as the infecting matter remains localised experience amply shows that cauterisation or excision can safeguard the subject from all bad consequences.

SUPPURATION IN THE ABDOMEN AND HIP-JOINT DUE TO AN ARTERY FORCEPS LEFT IN THE PERITONEAL CAVITY AFTER OVARIOTOMY.

AT the meeting of the Société Médicale des Hôpitaux of Paris on March 9th M. Le Gendre and M. Genévrier reported the following remarkable case in which an artery forceps was left in the peritoneal cavity after ovariotomy and caused suppuration which involved the right ilium and hip-joint. The patient was taken to hospital in the autumn of 1905. She had been in bed for three months and treated for phlebitis of the right leg, a diagnosis which was confirmed. There were considerable œdema of the limb and intense pain at its proximal extremity. In the inguinal region was a particularly painful spot and the lymphatic glands were enlarged. In December the hip was the seat of a diffuse swelling. Under the tense skin was a bluish network of a collateral venous circulation. The hip was very tender and gave a sensation of deep resistance. On vaginal examination the right fornix was found to be tender. The right lower limb became adducted and rotated internally and fixed in this position so that the hip joint did not permit of the slightest movement. Secondary deviations of the pelvis and spine took place. Osteosarcoma of the hip was diagnosed. Spontaneous pain became more and more intense and morphine was given. The cachexia increased and the patient died on Feb 27th. The necropsy revealed an entirely unexpected condition. Amidst the coils of intestine and covered by adhesions

Dr. Fanago observed the same effect when using urotropine: the bacteria did not entirely disappear. When the urine has become clear under the use of hetraline the drug should be continued for a time, since spores probably remain in the tissues and may thus be protected from the action of the hetraline. In gonorrhœa the drug does not seem to be of value, the gonococci not being destroyed by its action. From the reports of the cases given in this pamphlet further trials of hetraline are indicated. The results hitherto obtained seem to be encouraging.

A POISONOUS FLAVOURING AGENT.

WE quite agree with the jury in the following extraordinary case that nitro-benzene should be included in the schedule of poisons under the Pharmacy Act. In a biscuit factory at Truro a boy drank some almond flavouring which resulted in his death. The "essence" proved to be nitro-benzene which appears to be used as a flavouring agent and as a substitute for oil of bitter almonds. Nitro-benzene is a very powerful poison and the inhalation of even small quantities of the vapour has proved fatal Taken internally, 15 grains have been known to kill an adult, the poisonous symptoms resembling those produced by prussic acid. Spirituous liquids intensify its poisonous action. The use of nitro-benzene in food substances should be prohibited forthwith. This case affords another instance of the impudent disregard so often shown by substitute-mongers for the health of the public and honest dealing.

HOSPITAL APPOINTMENTS AND LIMITATION OF PRIVATE PRACTICE.

AS we mentioned in THE LANCET of March 24th at the annual meeting of the governors of the Cardiff Infirmary it was resolved that authority should be given for an addition to the honorary staff of one or more surgeons to the ear, nose, and throat department. As to this portion of the resolution we have nothing to say but it was further resolved that the gentlemen elected to these positions will be required to confine themselves in their private practices to diseases of the ear, nose, and throat. It is always highly desirable that in a hospital the several spheres of practice should be clearly marked out, for if this is not done much ill-feeling may arise, but we are not aware of any previous attempt to limit so closely the private practice of a member of the honorary staff of a hospital. The practising of pharmacy is, of course, often mentioned as not permitted and Members of the Royal College of Physicians of London were at one time not allowed to practise midwifery, but these restrictions are hardly akin to those mentioned above and it is a little difficult to know where to draw the line. For instance, would every disease in which the ear is affected be a disease of the ear? Post-influenzal infection of the mastoid would, we presume, be considered a disease of the ear. Again, if the aural surgeon is performing the complete mastoid operation and he finds reason for thinking that there is a septic thrombosis of the lateral sinus, would he or would he not be allowed to continue the operation so far as to incise the thrombosed sinus or to tie the internal jugular vein? It will be seen that difficulties and doubts may arise as to the limits of even such a special department as the ear, and the same must be the case with diseases of the throat or nose. What are the limits of the throat? The term, we suppose, includes the pharynx, the larynx, and the œsophagus, but how much more it is hard to say. We should like to know who is to be the arbiter as to the boundaries of these special departments; but apart from this point we do not consider the regulation a sound one or calculated to improve the professional position of medical men. It should be left to the individual feeling and discretion of medical men to set limits to the scope of their private practice.

A NEW FORM OF CONSCIENTIOUS OBJECTION.

AT Exeter recently the magistrates refused certificates for exemption from vaccination to an applicant who failed to satisfy them that he had a "conscientious objection" within the meaning of the Act. The person seeking exemption is described in the report before us as Mr. J. McIntosh, a dental surgeon in practice in the city of Exeter, and the ground upon which he made his application was the alleged discovery that vaccination "destroyed the second set of teeth and that was why so many people had bad teeth at the present time. Vaccination set up an eruptive fever just at the time that the second teeth were forming. He had treated 5000 people and 10 per cent. suffered through vaccination." The *Morning Post* informs us that a mandamus was threatened to compel the magistrates to give effect to this statement of the applicant's belief as a conscientious objection. This is a legal question which we must regard as *sub judice*. With regard to the views of Mr. McIntosh and his description as a dental surgeon, it is sufficient to say that his name does not appear upon the Dentists Register for 1906 as of Exeter, nor in the dental section of the Medical Directory for 1906, nor under Exeter in the Dental Annual for 1906. The view held by Mr. McIntosh is not accepted by the large majority of dentists and there is no pathological evidence to support his contention.

"PHILADELPHIA CLINIC FOR THE HOME TREATMENT OF CONSUMPTION."

ATTEMPTS are now being made in several countries to supplement the treatment of hospital patients by an endeavour to improve the hygienic conditions of their domestic surroundings. In order to be successful such an organisation has to be most complete and many difficulties must necessarily stand in the way. We have received a leaflet giving some of the details of a scheme which is to be tried in Philadelphia but unless more elaborate means are adopted the results will probably not be very satisfactory. The originators of the "clinic" point out that the hospitals in Philadelphia are doing their utmost to help in combating the almost unvarying death-rate in that city, but it is clear that they can never solve the whole of the problem. "For if they were to-day enabled to cure the eight or nine thousand consumptives who are annually sick or dying in this city, where hospital room does not exist for 1 in 70 of that number, another crop equally large would spring up to-morrow, unless pauperism, squalor, living in damp, unventilated, and overcrowded dwellings, deficient care while recovering from the effects of colds, of other diseases, and of injuries and unsanitary influences of all sorts are abated at the same time." The latter part of the above quotation would apply to all large cities and some organised endeavour to cope with these difficulties is urgently and constantly needed. The object of the clinic which is to be founded in Philadelphia is to treat the patients in their own homes, when they are able to contribute to their own maintenance, and also to undertake a "general hygienic care of their physical and social interests." Also, it is proposed to examine the members of families in which pulmonary tuberculosis has occurred in order to ascertain whether any of them show evidence of the disease. The board of managers has appointed a staff of physicians who will hold daily clinics between 3 and 4 o'clock every afternoon for the treatment of patients permitted to override the apparent meaning of the Coroner's Act, 1887. The doubt as to this, and the whole unfortunate dispute between the coroner in an important London district and the medical men practising therein, point to an insufficiency and want of clearness in the statute mentioned, and it may be suggested that whichever side may eventually be held to have been in the right those who are unsuccessful will more or less urgently demand some legislative change. The subject matter which gives rise to the inquest, the suspicion that a person has died a violent or an unnatural death, or a sudden death whereof the cause is unknown, is not stated in the most lucid possible manner for the guidance of the coroner, nor do all the circumstances in which an inquest might well be held appear to be included. The information required by a coroner in order that he may decide whether there shall be an inquest or not should be obtained from a medical man but no power to pay for such information is given. As to this a letter from "Country Doctor" at p. 1014 suggests the proper course to be adopted. The denial of fees to medical officers of lunatic asylums and hospitals summoned as witnesses may be cited as another point of interest to the medical profession as well as the disagreeable discussions which take place when a coroner believes that a medical man has given or has withheld a death certificate wrongly. Other matters besides differences of opinion of this kind show that not only the Coroners Act, 1887, should be reconsidered but that the law relating to the registration of deaths should be brought into harmonious combination with the provisions of any new one. The Act of 1887 continues the old qualification for the office of coroner that the candidate "shall be a fit person having land in fee sufficient in the same county whereof he may answer to all manner of people," and although this may be disregarded in practice it would presumably be deliberately omitted from a new measure with the substitution of some conditions as to the fitness by training and experience of the person appointed for his office. The necessity for medical qualifications for all coroners would naturally be urged by the medical profession when this point came to be dealt with. The coroners of to-day include many men whose knowledge and experience would entitle them to be heard upon questions affecting their office and fresh evidence from these would be available to supplement opinions already at the command of the legislature. A Bill dealing with any *one* of the points enumerated singly, or such a one as would merely relieve a jury of the "unpleasant" formality of "viewing" a dead body, would tend to delay rather than to expedite general and effective reform. The British Medical Association is known to favour legislative reform.

A Child "en Ventre sa Mere."

In THE LANCET of June 10th, 1905, p. 1602, was recorded a decision of Mr. Justice Swinfen-Eady in the divisional court that in a certain technical case a child born three weeks after the decease of the testator was excluded from certain provisions of a will as not being "born in the lifetime" of the author of the will. This decision caused surprise at the time and was regarded as creating an exception to the general rule enunciated in Bacon's Abridgment: "It is now clearly settled that a child *en ventre sa mere* is a life in being to all intents—except in the case of a descent at common law." An appeal was instituted and allowed on March 8th by the Master of the Rolls and Lords Justices Romer and Cozens-Hardy. They said that the principle to be deduced from a long series of decisions was that *primâ facie*, in the absence of a sufficiently weighty consideration to the contrary, for the purposes of devolution of property in connexion with intestacies or wills, no distinction ought to be drawn between a child born at a particular time and a child at that time *in utero* and subsequently born alive—and in particular in the case of wills no such distinction ought to be made unless the context required it.

ASYLUM REPORTS.

Hants County Asylum (*Report for the Year 1904*).—The average number resident at this asylum was 1094, the sexes being nearly equally divided. Whilst showing considerable fluctuations the number resident has, with one exception, been above 1000 since 1893, and is now 78 above the figure in that year. The admissions numbered 197, or 22 less than in the previous year; the admissions have not been so few since 1889 and have decreased steadily for the past three years. As regards causation, hereditary influence, direct and collateral, was ascertained in less than 20 per cent. of the admissions. This is a very low proportion and it may be doubted whether this figure accurately represents the incidence of the hereditary factor. The other causes given are not noteworthy. The percentage of recoveries on admissions was 37·6, the mean annual figure for the period during which the asylum has existed being 32·8. The percentage of deaths on the average number resident was not more than 8, which is lower than it has been for nine years. Tuberculosis accounted for about 28 per cent. of the deaths, a high proportion. Amongst other causes we notice peritonitis due to fæcal obstruction as responsible for one death. This is a very unusual cause and requires, we think, elucidation. Necropsies were performed in 76 per cent. of the deaths. The medical superintendent, Dr. T. B. Worthington, from whose report the above extracts are made, remarks that the number of melancholic and actively suicidal cases brought for treatment is much larger than that of the maniacal and seems to increase yearly. The health of the asylum was good; colitis occurred in only four cases and enteric fever in one. The annual report of the Commissioners in Lunacy speaks favourably of the state of the institution.

Nottingham City Asylum (*Report for the Year 1904*).—The average number resident in this asylum during 1904 was 759. The admissions numbered 168, the discharges 65, and the deaths 81. The percentage of recoveries on admissions was 36·94, the average for the past 25 years being 39·4. The percentage of deaths on the average number resident was 10·67, the average for the period mentioned being 10·36. During the past 20 years the numbers resident have increased from 350 to 759. The female division is overcrowded and the provision of further accommodation is under consideration. The character of the admissions was very unfavourable, fully 45 per cent. presenting little or no prospect of recovery. According to Table X., which deals with the causes of insanity in the admissions, 193 cases were admitted, whereas the report gives the figure as 168. In 31 cases the cause appears under the heading "other bodily diseases and disorders." This is a rather large proportion, and it would be conducive to more accurate knowledge were these conditions referred to more fully in this and other asylum reports. Hereditary predisposition was found in the low proportion of 21 per cent. of the cases, and alcoholic excess in 12 per cent. according to the report, but the percentage occurrence, based upon 168 admissions, would give 11·4 per cent. Mr. Evan Powell, the medical superintendent, reports that the general health has been good; no infectious disease occurred and no death took place as a result of insanitary conditions in the building. The death-rate from pulmonary tuberculosis has, however, risen from 7·6 per cent. of all deaths last year to 14·8 per cent. this year, though it is still below the average for asylums of similar size. The committee states that it feels it a duty to consider the desirability of providing separate accommodation for private patients of the middle class. This view is gradually being adopted by the managing bodies of county asylums. This asylum is economically managed, the weekly charge being the low one, for city and borough asylums, of 10*s.* The Commissioners in Lunacy report favourably of the condition of the institution.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8933 births and 5150 deaths were registered during the week ending March 31st. The annual rate of mortality in these towns, which had steadily declined in the four preceding weeks from 17·4 to 15·8 per 1000, rose again last week to 17·0. In London the rate was 18·5, while the average rate in the 75 other large towns did not exceed 16·3. The lowest death-rates in these towns during the week were 8·3 in Grimsby, 9·0 in Hornsey, 9·4 in Willesden, and 9·7 in Leyton; the highest rates were 21·3 in Birmingham, Bootle, and Bury, 21·4 in Huddersfield, 22·1 in Liverpool, 22·2 in Blackburn, 22·8 in Hanley, 23·3 in Warrington, and 24·5 in Middlesbrough. The 5150 deaths in these towns included 492 which were referred to the principal infectious diseases, against 469, 435, and 414 in the three preceding weeks; of these 197 resulted from measles, 158 was a blackened artery forceps. It lay perpendicularly in the right iliac fossa with the handles approaching the umbilical region. The blades lay in a sheath of adhesions which contained a little pus. The tip of the forceps pressed against the ischio-pubic rami below the femoral vessels. At this point the bone was bare and the sheath of adhesions in which the forceps lay was continued under the femoral arch. A probe passed down this canal arrived at the external surface of the ilium, which was also bare. The region of the hip was exposed by a large incision and the joint was found to be destroyed completely. The head of the femur, the acetabulum, and the external surface of the ilium were profoundly necrosed. The surface of the bones was blackish. Sanious and fœtid pus, similar to that which bathed the forceps, flowed out. Evidently a communication with a stercoral abscess existed. Six years before death an operation had been performed in a foreign country. This the necropsy showed was double ovariotomy.

ON Wednesday, April 11th, a discussion will be held at the Hunterian Society, London Institution, Finsbury-circus, London, E.C., at 8.30 P.M., on Syphilis, to be opened by Mr. Jonathan Hutchinson. The disease will be considered in relation to mental disease, the nervous system, and the viscera. All medical men are cordially invited. At the following meeting of the society the discussion will be continued in relation to congenital syphilis, syphilis of the eye and the skin, and general treatment.

MANY of our readers will be glad to hear that the MS. of Dr. John Brown's famous little story, "Rab and His Friends," which was sold by Messrs. Sotheby, Wilkinson, and Hodge last week for £40, was secured by Mr. Quaritch for some Edinburgh medical men who intend to present it either to the library of the Royal College of Physicians of Edinburgh or to that of the University.

A TELEGRAM from the Governor of Hong-Kong received at the Colonial Office on April 2nd states that for the week ending March 31st there were 27 cases of plague and 25 deaths from the disease.

THE forty-sixth annual dinner of King's College (University of London) will be held at the Hotel Cecil on Monday, May 7th. Mr. Justice Grantham will occupy the chair.

King Edward's Hospital Fund has received a cheque for £10,000 for the capital fund through a bank, with instructions that the donor desires to remain anonymous.

BRITISH MEDICAL BENEVOLENT FUND.

AT the monthly meeting of the committee held on March 20th 15 applications were considered and sums amounting to £176 voted in relief. Mr. Parker Young was unanimously re-elected chairman for the ensuing year and the annuity subcommittee was re-appointed for the same period. Appended is a short abstract of the cases.

1. *Daughter, aged 56 years, of* late M.R.C.S., who practised in Wiltshire. Is given a home by brothers in return for services but receives no salary. Health delicate Relieved five times, £84. Recommended by Mr. T. H. Cheatle. *Voted* £12 in 12 instalments.

2. L.S.A., aged 62 years. Used to have an excellent practice in the south-west of London but the neighbourhood degenerated and applicant's difficulties were increased by severe *and prolonged* illnesses in his family. He is now endeavouring to establish a cash practice and has exhausted the proceeds of the lease of his former house in doing so. Recommended by Dr. J. Mitchell *Bruce*, vice-president. Voted £18 in 12 instalments.

3. *Widow*, aged 48 years, of L.R.C.P. Edin., L.R.C.S Glasg., who practised in Cumberland. Small capital left at husband's death was spent in paying his debts, and applicant's children, although doing all they can to help, are unable to contribute sufficient to support her. Recommended by Dr. G. H. Hume. Voted £10 in two instalments.

4. Widow, aged 63 years, of M.R.C.S , L S.A., who practised in New South Wales. *For 15 years since her husband's death* applicant has supported herself as cook in a large lodging house kept by a friend but now has to give up her post as the house no longer pays expenses. Recommended by Dr. W. Travers. Voted £14 in 12 instalments, the first instalment to be £3.

5. Widow, aged 48 years, of L R.C P., L.R.C.S. Edin., who practised in London. Quite unprovided for at husband's death; tries to support herself by needlework and proposes to obtain employment which will give her a home. Relieved *once*, £12. *Recommended by Dr. Mitchell* Bruce. Voted £5 in one sum with leave to apply again in six months.

6. *Widow, aged 61 years, of* M.D., *C.M.* Glasg., who practised in Lancashire. Received £14 a year from a Working *Ladies'* Guild and a few shillings a week from a son who is a railway signalman. Relieved six times, £72. Recommended by Miss Farquhar. Voted £12 in 12 instalments.

7. Widow, aged 45 years, of M.B , C.M. Edin., who practised in Perthshire. Income £20 a year and *supplements this and the slight* help given by a relation by taking boarders in the summer. Six children, aged 15 to eight, two being at an institution. Relieved seven *times*, £78. *Recommended by Dr. A. R. Urquhart*, honorary local secretary. Voted £12 in 12 instalments.

8. Widow, aged 47 years, of L.R.C.P. Edin., M.R.C.S. Eng., who practised in Herefordshire. Five children, only two of whom are able to contribute to their maintenance. Just manages to make both ends meet by taking several boarders. Husband was totally incapacitated for several years before death and applicant was consequently left unprovided for. Relieved three times, £48. Recommended by *Surgeon Lieutenant-Colonel Deeble. Voted £12 in 12 instalments.*

9. Widow, aged 55 years, of L.F.P.S. Glasg., who practised in London. Ten children, of whom one is an invalid, two are out of work, and two at school, the rest contributing what they can for themselves and the maintenance of the rest of the family. Relieved seven times, £108. Recommended by Dr. J. O. Adams, vice-president. Voted £12, in 12 instalments.

10. Widow, aged 42 years, of L.R.C.P., L.R C.S. Edin., who practised in Cardiganshire. Left unprovided for at husband's death and was dependent on her father, now deceased. Two children in the merchant service, one just self-supporting, the other only apprenticed. Relieved once, £12. Voted £3 immediately and *case to be further considered* at the next meeting.

11. Daughter, aged 58 years, of M.R.C.S., L.S.A., who practised in Lancashire. Was comfortably provided for at father's death, but the capital was misappropriated by the trustee, and applicant now has no means of subsistence Relieved once, £18. Recommended by Dr. J. E. Nevins, honorary local secretary, and by Dr. J. Cameron. Voted £18 in 12 instalments.

12. *Widow, aged 45 years, of* L.R.C.S , L.S.A., who *practised* in Durham. No income; endeavours to support herself by needlework. Indifferent health. Two children; one just self-supporting, the other a school-girl. *Relieved four times, £35. Recommended by Mr. Henry* Power. Voted £12 in 12 instalments.

13 Widow, aged 62 years, of L.R.C.P., L.R.C.S. Edin., who practised in Glasgow. Only income £10 a year from a charity; endeavours to support herself by taking boarders, but health so bad that at present she can only look after one. Only child, a daughter, has just finished a course of training as a teacher and is waiting for a post. Relieved seven times, £24. Recommended by Dr. Joseph Bell, honorary local secretary, and by *Sir Patrick Heron* Watson. *Voted* £12 in 12 instalments.

14. Widow, aged 44 years, of M.R.C.S., L.S.A., who practised in Sussex. No income; receives a home and small *salary for services as* working housekeeper, but applicant's health is so indifferent that she often has to pay for a substitute. Children unable to help. Relieved seven times, £88. Recommended by Dr. R. Shingleton Smith. Voted £12 in 12 instalments.

15. *Daughter*, aged 50 years, of M.R.C.S., L.S.A., who practised in London. No income; allowed £18 a year by a sister. Health too precarious for continued exertion. Relieved eight times, £89. Recommended *by* Mr. W. Bramley Taylor and Mr. Frank Hewkley. Voted £12 in 12 instalments.

MEDICINE AND THE LAW.

Changes in the Law regulating Inquests.

A PRIVATE Bill which has been introduced in the House of Commons and has been mentioned as being one which may be pressed forward has for its object the relief of coroner's juries from the obligation to view the dead bodies forming the subject of their inquiries. The matter has often been discussed and it is not likely that anyone would seriously oppose such a measure, but the system has been in existence from time immemorial and its alteration cannot be said to be of urgent importance. On the other hand, amendments of the law of a trifling character made from time to time complicate it needlessly and may have the effect of postponing more important changes by removing minor grievances and by inducing a feeling that no further improvement of the existing state of affairs is needed. The medical profession, particularly those members of it who practise in the division in which Mr. Troutbeck presides as coroner, are awaiting with interest the next stage in the proceedings relating to the payment of fees to Dr. Freyberger. The question at issue as to this seems to depend largely upon how far any discretion which the coroner may possess under the common law with regard to the summoning of medical witnesses is

The Order of the Osmanieh.

The King has given to the undermentioned officers permission to accept and wear the Imperial Ottoman Order of the Osmanieh, Fouth Class, which has been conferred upon them by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey, in recognition of valuable services rendered to His Highness: Major John Herbert Rivers, R.A.M.C., and Captain Hamilton George Frampton Stallard, R.A.M.C.

The Appointment of Surgeon-General in India.

The *Army and Navy Gazette* of March 31st says: "The officers of the Royal Army Medical Corps have gained the day in the matter of the surgeon-general's appointment in India, over which, as we have already stated, the War and India Offices have been fighting for nearly a year. This decision will take Surgeon-General Slaughter to Bombay, vice Gubbins, for the former officer, pending this decision, has remained on at Colchester (a colonel's appointment). Arrangements can thus now be made for the appointment of a successor to Surgeon-General W. H. Macnamara at Aldershot whose retirement by age falls due in June."

Appointment of Dental Surgeons.

Mr. W. J. F. Middlemiss, L.D.S. Edin., has been appointed a dental surgeon to the troops in Ireland and Mr E. H. Wyand, L.D.S. Eng., to the troops at Aldershot.

Correspondence.

"Audi alteram partem."

THE ETHICS OF THE MEDICAL PROFESSION IN RELATION TO SYPHILIS AND GONORRHŒA.

To the Editors of THE LANCET.

SIRS,—I hope that Mr. Campbell Williams's able address, the correspondence between him and Mr. Dudley Burney, and your annotation, "The Prevention and Early Treatment of Syphilis," will lead to something practical being done. In the *brochure* to which you kindly referred I showed seven years ago that special hospitals and special wards in general hospitals for these diseases were becoming a vanishing quantity, and as regards wards in general hospitals this has been accentuated, ward after ward in the London hospitals having been closed against the patients formerly received and devoted to medical and surgical cases. The general public has never shown much sympathy for such hospitals. Whether this be due to the odium attaching to the word "lock" or to any other cause I do not know. As regards lock wards in general hospitals I would ask with all respect whether the medical and surgical staff of each hospital is free from blame. Patients with those diseases are seen as out-patients in every general hospital. No one will dispute the importance of all students being taught how to diagnose promptly and to treat these diseases. Is this done? Among the out-patients are many cases of syphilis and gonorrhœa. Are they seen by the assistant surgeon who has had the greatest experience of them and who is most competent to teach the students? Is there a special day for seeing these cases? Cannot the governing body of each hospital be induced by the medical staff to set apart at least a few beds for cases that cannot be efficiently treated as out-patients? Surely there is something very inconsistent in refusing to admit a patient, male or female, suffering from primary syphilis in a very aggravated form and having in the medical wards patients suffering from syphilitic diseases of the brain, the lungs, the heart, &c., and in the surgical wards men suffering from the results of repeated attacks of gonorrhœa.

In Liverpool the only wards for the reception of patients suffering from these diseases are those of the local workhouses, Liverpool, West Derby, and Toxteth. The same must be true of many another large town and city in England. These facts, which are indisputable, strongly emphasise the recommendation of the committee on the deterioration of health that a Government inquiry should be held as to the present provision for the treatment of pox. It concerns all members of the profession. Obstetricians and gynæcologists see the effects of syphilis in innocent sufferers, married women and children. Physicians, surgeons, and specialists of all kinds could give valuable evidence of the far-reaching nature of syphilis and of gonorrhœa. The baneful effect of these two poisons—the syphilitic and gonorrhœic toxins—are almost unlimited.

I am most anxious that this letter should be read, should you be kind enough to afford me the space. Hence, I do not wish to make it long and have omitted all reference to the moral and social points. I hope that some medical or lay member of the House of Commons may be induced to put a question to the President of the Local Government Board asking him if he will grant the inquiry asked for.

I am, Sirs, yours faithfully,

Liverpool, March 31st, 1906. F. W. LOWNDES.

To the Editors of THE LANCET.

SIRS,—Whether statistics are like alchemical formulæ or whether it is possible to get trustworthy statistics showing that the percentage incidence of venereal disease is really alarming will never alter the fact that syphilis is the cankerworm of a large majority; that the tissues built up in mature and *embryonic life, in contact* with the spirochæta, are so spoilt and "jerry-built" as to be a ready prey to stress and to alcohol, nay, almost any known malady that comes under the nomenclature of disease. Then, logically speaking, with common-sense principles of the present day, is not preventive *medicine* the proper course of treatment? But, I ask, how can the practice be governed, even if legislation were brought into fashion under a system of notification? Supposing every man and woman so notified were kept under surveillance would it not end as a mare's nest, gratifying, no doubt for the time being, a few of us?

No, Sirs, society will never tolerate a universal Contagious Diseases Act, however desirable or consistent it may be thought fit to place such military stations as Aldershot, Woolwich, &c., under sexual supervision. Filthy in mind and body as some prostitutes appear, still the class of men whom they appeal to are, in many instances, as equally depraved. Beastliness is not the word. And I maintain that a woman's privacy should not be unprotected more than that of a man's in any class of society to which the word prostitution, relatively speaking, is applicable. Just imagine for a moment what a state of chaotic uproar it would lead to should general notification of syphilis become law. Thus my argument is to leave things as they are in hopes that the swing of the pendulum will affect even sexual matters.

It would indeed be satisfactory to know who is the greater sinner in sexual matters, the man or the woman; whether a large amount of prostitution is not the outcome of man's infidelity; and whether, instead of labeling the woman, it should not be the other way about. These are my views on the subject and which I consider dishonourable men might *take to heart; and if* they cannot or do not wish to comply with the decent laws of sexual *congress* let them pay the penalty and the weight of this ethical question in civilised Great Britain. Indirectly, I think, the danger zone is man himself, when we regard the spread of syphilis, especially in my mind the worse type—viz., congenital. If a man sows wild oats and he comes to grief, why should human breeding suffer? This is the crux of the whole matter so far as the deadly effects of syphilis are concerned.

Those who are of the *insane stock* and who do not breed do no one any harm; so it is with those who *have* contracted syphilis. Thus I shall always condemn marriage at the altar by a man who has acquired this disease. And I would support any Bill that the parliament of the profession might bring forward as a preventive step for decreasing the degenerate class, believing that congenital syphilis is the spoiling agent in many cases.

In conclusion, although syphilis may be contracted accidentally, still there is a potent disease which, considering all circumstances, is a death-blow to healthy breeding. Among men of a *high* ethical standard marriage at the altar, considering these circumstances, would be out of the question. But such recommendation of healthy breeding would not appeal to another class whose ethical standard is low. Therefore men who have had frequent intercourse with a variety of women and who have acquired syphilis should not be representative human breeders. On the contrary, they had better remain as bachelors and live with the class of women whose society they have so long encouraged instead of ravaging the genealogical tables of healthy women.

from whooping-cough, 46 from diphtheria, 39 from diarrhœa, 32 from scarlet fever, and 20 from "fever" (principally enteric), but not one from small-pox. No death from any of these infectious diseases was registered last week in Bournemouth, Reading, Ipswich, Norwich, Plymouth, Stockport, Wigan, Rochdale, or in seven other towns, while they caused the highest death-rates in Liverpool, Preston, Handsworth, Wolverhampton, Blackburn, Smethwick, and Bury. The highest rates of mortality from measles occurred in Bristol, Newcastle-upon-Tyne, Yarmouth, Tottenham, Blackburn, Preston, and Bury; from whooping-cough in Warrington, Aston Manor, West Bromwich, Handsworth, and Smethwick; from diphtheria in St. Helens and Leicester; and from diarrhœa in Oldham. The mortality from scarlet fever and from enteric fever showed no marked excess in any of the large towns. No death from small-pox was registered during the week either in London or in any of the large provincial towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals, which had been six, seven, and ten at the end of the three preceding weeks, declined again to eight at the end of last week, no new case having been admitted during the week, against five in the previous week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday last, March 31st, was 2386, against numbers declining from 2628 to 2434, on the four preceding Saturdays; 223 new cases were admitted during the week, against numbers declining from 273 to 234 in the four preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 334 and 320 in the two previous weeks, rose again to 337 last week, and exceeded the corrected average for the corresponding week in the four preceding years by 20. The causes of 57, or 1·1 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, Hull, Newcastle-on-Tyne, West Ham, and in 48 other smaller towns; while the highest proportions of uncertified deaths were registered in Liverpool, Birmingham, Manchester, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·3, and 18 0 per 1000 in the two preceding weeks, rose again to 18·9 during the week ending March 31st, and exceeded by 1 9 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·8 and 16 5 in Leith and Edinburgh to 21·4 and 21·8 respectively in Greenock and Dundee. The 647 deaths in these eight towns included 27 which were referred to measles, 11 to whooping-cough, 12 to diarrhœa, six to scarlet fever, four to diphtheria, two to "fever," but not one to small-pox In all, 62 deaths resulted from these principal infectious diseases last week, against 81 and 57 in the two preceding weeks. These 62 deaths were equal to an annual rate of 1·8 per 1000, which exceeded by 0·2 the mean rate last week from the same diseases in the 76 large English towns The fatal cases of measles, which had been 37 and 20 in the two preceding weeks rose again to 27 last week, of which 14 occurred in Glasgow, seven in Edinburgh, and two both in Dundee and Paisley. The fatal cases of whooping-cough declined again last week to 11, from six and 16 in the two previous weeks, and included seven in Glasgow and two in Dundee. Three of the four fatal cases of diphtheria were registered in Glasgow and of the 12 deaths referred to diarrhœa five were returned in Glasgow and two both in Edinburgh and Dundee. The deaths referred in the eight towns to diseases of the respiratory organs, which had been 125 and 128 in the two preceding weeks, declined last week to 103, and were within one of the number returned from the same diseases in the corresponding week of last year. The causes of 16, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·1 and 25·6 per 1000 in the two preceding weeks, further rose to 26·1 during the week ending March 31st. During the 13 weeks of last quarter the death-rate averaged 22 9 per 1000; during the same period the mean death-rate did not exceed 16·6 in London and 17·4 in Edinburgh. The 190 deaths of persons belonging to Dublin registered during the week under notice showed an increase of four upon the number in the previous week and included ten which were referred to the principal infectious diseases, against ten and four in the two preceding weeks; of these, three resulted from diphtheria, three from "fever," two from whooping-cough, two from diarrhœa, but not one from small-pox, measles, or scarlet fever. The ten deaths from these infectious diseases were equal to an annual rate of 1·4 per 1000, the death-rates last week from these diseases being 1·8 in London and 2·0 in Edinburgh. The three fatal cases of diphtheria in Dublin exceeded the number in any previous week of last quarter; and it is noteworthy that seven deaths from "fever," probably enteric, were registered during the last three weeks of the quarter. The 190 deaths in Dublin last week included 40 of infants under one year of age and 54 of persons aged upwards of 60 years; the deaths of infants showed an increase, and those of elderly persons a decline, compared with the numbers in the previous week Four inquest cases and three deaths from violence were registered; and 87, or no less than 46 per cent. of the 190 deaths, were recorded in public institutions. The causes of 12, or 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified:—Fleet Surgeon G. A. S Bell to the *President*, for hospital course. Staff-Surgeons: F. Fedarb and E G. E O'Leary to the *President*, for hospital course; R. W. Stanistreet to the *Doris*; and H. E. Fryer to the *Tyne*. Surgeons: P. W. MacVean to the *Sapphire II.* and A. T. Gailleton to the *President*, for hospital course.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Edward Wentworth Luther has been placed on the Retired List at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated April 1st, 1906).

ROYAL ARMY MEDICAL CORPS.

Colonel Montgomerie Blennerhassett, C M.G., retires on retired pay (dated April 4th, 1906).

INDIAN MEDICAL SERVICE.

The King has approved of the retirement of the undermentioned officers:—Lieutenant-Colonel Frederick William Wright, D.S.O. (dated Dec. 7th, 1905); Lieutenant-Colonel Eugene Cretin (dated Dec. 31st, 1905); Lieutenant-Colonel Gerard Macklin Eccles McKee (dated March 14th, 1906).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel Robert T. C. Robertson, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated April 4th, 1906).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Edinburgh (City): James Hunter Harvey Pirie (formerly Second Lieutenant, Royal Field Artillery), to be Surgeon-Lieutenant (dated March 31st, 1906).

Royal Engineers (Volunteers): 1st Sussex: Surgeon-Captain A. H. Croucher resigns his commission (dated March 31st, 1906).

Rifle: The Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment): Surgeon-Captain J. A. Clark to be Surgeon-Major (dated March 31st, 1906). 2nd Volunteer Battalion the Northumberland Fusiliers: Supernumerary Surgeon-Lieutenant F. N. Grinling (Commanding Tyne Volunteer Infantry Brigade Bearer Company) to be Surgeon-Captain, remaining supernumerary (dated March 31st, 1906). 20th Middlesex (Artists') Volunteer Rifle Corps: Surgeon-Captain C. S. de Segundo is granted the honorary rank of Surgeon-Major (dated March 12th, 1906).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Seaforth and Cameron Bearer Company: Captain J. Macdonald to be Major (dated March 31st, 1906).

base conclusions. Mr. Moynihan himself has, I believe, adopted the no loop method only within the last two years, too short a period in which to judge of the after results. My contention is that at the present time we are not entitled to maintain that experience is conclusive as to the status of the no-loop method, nor can I admit that "every argument" is in favour of it. The no loop method is, at least so it seems to me, wrong in principle, as it must be mechanically incorrect to unite a portion of the jejunum close to its origin to a moveable organ like the stomach. That this is not a hypothetical objection is proved by a case recently recorded by Munford[1] in which death ensued owing to the anastomosis being torn apart by the contraction of the stomach. Such an accident can hardly occur if a loop be left between the origin of the jejunum and the site of the anastomosis.

With regard to the occurrence of internal hernia, Mr. Moynihan asserts that such an occurrence is impossible if the edges of the mesocolon are stitched to the jejunum. Impossible is a strong word to use in connexion with the abdominal cavity, a region about which prophecy is extremely hazardous. Mr. Moynihan himself has, so I am informed, adopted this plan for less than two years and since in some of the recorded cases of gastro-jejunostomy (including one of Mr. Moynihan's own) internal hernia has not occurred until *after an interval of two years*, surely it is too early to speak positively as to the impossibility of internal hernia when the mesocolon is stitched to the jejunum. In the absence of any direct evidence on the point I think we may be sceptical as to whether the insertion of three stitches will invariably secure permanent and efficient closure of the opening into the lesser sac.

Mr. Moynihan next deals with the subject of regurgitant vomiting. He admits that the obstruction is at the anastomotic opening and then concludes: "The cause of this obstruction I submit, therefore, is to be found in the loop." I confess I do not follow this reasoning. Why if the obstruction be at the anastomotic opening should the loop play any part in its production, unless, indeed, Mr. Moynihan maintains that the obstruction is secondary to "water-logging"? Be this as it may, my contention is that regurgitant vomiting is a preventable complication, and there is no evidence that it is more common after anterior than after posterior gastro-jejunostomy.

Next as to peptic jejunal ulcer. Mr. Moynihan takes exception to my explanation of the fact that more instances of peptic jejunal ulcer have followed the anterior than the posterior operation—namely, that the anterior operation has been more frequently performed. He says, "it is almost certain that the posterior operation has been performed far more frequently." My answer is that a search through the records of the period 1831 to 1904 indicates that the anterior operation had been performed more frequently than the posterior, and the difference is probably sufficient to account for the larger number of jejunal ulcers which have followed the anterior operation. The important point, however, to which Mr. Moynihan does not allude is that peptic jejunal ulcer following the posterior is apparently a more serious complication than after the anterior operation.

Lastly, Mr. Moynihan states that "the choice of the posterior operation is the result of a considered and well reasoned opinion that it is a safer, and so far as the after-results are concerned a more successful, operation than the anterior, and established by long experience." Does Mr. Moynihan refer to the posterior operation with or without a loop? If he refers to the "no loop" method, advocated by Czerny and Petersen in 1901, he can scarcely maintain that it is an operation established by long experience. If, on the other hand, he refers to the posterior operation with a loop, I submit that the series of cases brought forward in my lectures shows that there is no evidence that the posterior operation is either safer, or more satisfactory as to the after-results than the anterior. I adduced records of patients who have lived in perfect health for 10, 12, 14, 18, and 19 years after anterior gastro-jejunostomy, some of whom have regained and maintained their normal weight. Can the advocates of posterior gastro-jejunostomy wish for better results than these?

Probably the last word has yet to be said as to the best method of performing gastro-jejunostomy, so that opinions, however considered and well-reasoned, must be accepted with caution and not accepted as final until they are supported by a long series of observed facts. For the present I submit that, whatever may be the case later, there is no conclusive evidence to show that the results, either immediate or remote, are better after the posterior than after the anterior operation. Until such evidence is forthcoming I shall continue to employ the simpler and, in my own experience, perfectly satisfactory anterior operation.

I am, Sirs, yours faithfully,

HERBERT J. PATERSON.

Upper Wimpole-street, W., March 30th, 1906.

THE QUESTION OF PAY HOSPITALS.

To the Editors of THE LANCET.

SIRS,—The general attention which is at the moment directed to schemes for providing public institutions for patients able to pay for their support has brought to light a good deal of evidence of the efforts made to deal with this subject—as long ago as 1831 in the case of St. Thomas's Hospital and 1854 in the case of Guy's Hospital. Smaller institutions may also claim to have to a great extent solved the problem and of these the Hampstead General Hospital was undoubtedly one of the first. Started as a home hospital in 1882 its special feature was that all patients were expected to contribute towards their support. It was found necessary later to provide free beds, the number of which has been increased now that the hospital has removed to the new building at Haverstock Hill. The experience of this institution goes to show that there is real need for beds for paying patients and when in the near future the hospital is enlarged to 115 beds it is intended to provide a special block with 20 beds for patients of this class, entirely seperated from the free wards.

The problem is made more difficult by the want of uniformity in hospital methods. Applications for admission here both to beds at the contributing rate of 12*s.* per week and the private rooms at the rate of £3 3*s.* per week have come from all parts of London. The former have necessarily been restricted to patients from the districts naturally served by the hospital and as regards the latter applications from the neighbourhood receive preference. These charges serve as a working basis, variations being, of course, made in special circumstances, and the provision of the beds at the higher rate being made for the benefit of those only who cannot properly afford the charges in an ordinary nursing home.

I am given to understand that at least one of the London hospitals which have accommodation of this kind restricts the practice to consultants but the course adopted in the Hampstead General Hospital, and which appears to be growing in favour, is that the patients shall be attended by their ordinary medical attendants, and that the necessary arrangements for the attendance of consulting physicians or surgeons shall be left in their hands.

I am, Sirs, yours faithfully,

ERNEST COLLINS,

Chairman of the Council.

Hampstead General Hospital, Haverstock Hill, N.W.,
March 28th, 1906.

ROYAL ARMY MEDICAL CORPS VOLUNTEERS (LONDON COMPANIES).—On March 31st a smoking concert was held by the London Companies of the R.A.M.C. Volunteers at their headquarters, 51, Calthorpe-street, Gray's Inn-road, to bid farewell to Mr. G. Small, late sergeant-major and senior instructor to the corps. During an interval in the proceedings a framed address and purse of money, subscribed by members of the corps past and present, were presented by the commanding officer, Colonel V. Matthews, who spoke warmly of Mr. Small's good influence on the corps during his connexion with it, which extended, off and on, over a period of nearly 22 years, ever since its first inception, and paid at the same time a graceful tribute to Mr. Small's high personal character. In thanking the donors, Mr. Small expressed the great pleasure that he experienced in accepting the gift and recalled many interesting incidents which occurred during his period of office. That there was much musical talent in the corps was evidenced by the lengthy nature of the programme provided, Colonel Matthews and most of the other officers taking an active part in the proceedings.

This, then, appears to me to be the ethics of the medical profession in relation to syphilis.

I am, Sirs, yours faithfully,
Alton, Hants, March 23rd, 1906. J. F. BRISCOE.

PERFORATED DUODENAL ULCER.

To the Editors of THE LANCET.

SIRS,—There are several points in the interesting communication on duodenal ulcer by Mr. S. Maynard Smith which appear to deserve remark.

In the first place perforated duodenal ulcers are by Mr. Smith divided into three classes, which may be briefly summarised thus: (1) acute perforation into the peritoneum with flooding of the whole sac; (2) acute perforation with flooding of part only of the sac; and (3) chronic perforation, which is either retroperitoneal or takes place into limiting adhesions. Although this method of classification is excellent from a clinical point of view, yet the use of the terms "acute" and "chronic" and also of the term "perforation" is open to criticism. There are two modes in which the "perforation" of a duodenal (or gastric) ulcer may occur: *rupture* by disturbance of adhesions, which is the rule; and *perforation* by extension of active ulceration, which is the exception. So called "acute perforation," whether it results in complete flooding of the peritoneal cavity, as in Class 1, or in a more limited intraperitoneal effusion, as in Class 2, in all the cases I have had the opportunity of critically examining has been due to tearing out of the floor of an ulcer by traction exerted on its adhesions. I think this accident is best expressed by the term "rupture." The mishap may be the result of muscular effort or of blows or be due to the traction exerted by a loaded or forcibly contracting stomach.

In the second place, there is a fact connected with these ulcers which is not sufficiently emphasised and which has some bearing on the feasibility of complete and satisfactory excision. In many instances the ulcers are not solitary and they are often placed one on the anterior and one on the posterior duodenal wall. Complete excision in such cases necessitates the removal of a complete segment of the bowel and if practised at the time of operation for perforation adds considerably to the gravity of a case already sufficiently serious.

Lastly, I should like to draw attention to the accuracy and great practical importance of the account given by Mr. Smith of the track followed by intraperitoneal suppuration due to rupture of a duodenal ulcer. We owe the description of the right kidney pouch to Mr. Rutherford Morison[1] who rightly recognised its importance. The influence attributed to the colon and to the configuration of the posterior abdominal wall in determining the track of intraperitoneal suppuration is in complete accord with the observations of Dr. A. E. Russell, Mr. Cuthbert S. Wallace, and myself, which are embodied in papers in the St. Thomas's Hospital Reports for 1897, the *British Medical Journal* of Feb. 8th, 1902, and more recently in the Transactions of the Medical Society of London, vol. xxviii. To Mr. Wallace is due, I believe, the credit for the term "peritoneal watersheds," which so admirably summarises the influence of the projection of the bodies of the vertebræ and of the iliac crests in determining the course of fluid collections in the peritoneal cavity of a patient lying in the supine position. I am, Sirs, yours faithfully,
Devonshire-place, W., March 30th, 1906. CHARLES R. BOX.

ETHYL CHLORIDE AS A GENERAL ANÆSTHETIC.

To the Editors of THE LANCET.

SIRS,—The interesting letters that you have published upon the subject of ethyl chloride indicate an unusually marked divergence of opinion. Some practitioners, in fact, at the present time appear to think that this anæsthetic should never be used, whilst others maintain that it is best in almost every case of short operation. Some freely argue that ethyl chloride is a perfectly safe drug and others see in it a source of *ready danger*. Now, Sirs, it seems to me undeniable that, on the one hand, there is no comparison between the relative safety of nitrous oxide and ethyl chloride and, on the other hand, there is equally no question that there are many cases where ethyl chloride is the most desirable anæsthetic to employ. So far as the question of safety goes, the matter is scarcely one of opinion. When the number of recorded fatalities that have been collected *from the thousands, almost the millions*, of cases of nitrous-oxide anæsthesia is balanced against the recorded fatalities due to ethyl chloride within the space of three years it is barely rational to maintain that the latter is on the same plane with the former so far as the question of safety is concerned. Moreover, it requires very small experience of anæsthetics to realise from clinical phenomena the totally different degree of potency of the two agents. The same may be said as regards the frequency of after-effects. Nevertheless, I agree entirely with those of your correspondents who uphold the value of ethyl chloride, if only they will admit that it is never to be used when nitrous oxide is available and is suited to the case. There is a special field, I believe, for ethyl chloride in cases of short operations upon persons who are not good subjects for nitrous oxide and also as a preliminary to ether in the case of these subjects when they are to undergo longer operations. As far as my own experience goes, it is in the cases of the alcoholics and of the muscular, high-coloured, thick-necked men—soldiers, *athletes, carmen, &c.—that ethyl chloride is particularly valuable.* Nitrous oxide, as is well known, does not give its best results with this type of individual, whether used alone or with air or with oxygen. With ethyl chloride, on the contrary, the requisite length and quiet of anæsthesia are easily obtained in such cases, and when the drug is used to precede ether from a Clover's inhaler it is equally satisfactory. In the case of the individuals to whom I am referring I believe ethyl chloride, if the dose is properly regulated, can be perfectly safely given in the sitting position; they are, of course, persons with powerfully acting hearts. In the case of small children, for whom ethyl chloride is now so often used for "tonsil and adenoid" operations, it is, as far as I have observed, very easy to get into danger with this anæsthetic.

I am, Sirs, yours faithfully,
J. BLUMFELD,
Senior Anæsthetist, St. George's Hospital, &c.
Cavendish-place, W., April 3rd, 1906.

To the Editors of THE LANCET.

SIRS,—*In reference to the above but more particularly* to Dr. R. A. Lankester's remark that "where it is necessary that above half-a-dozen teeth and stumps should be removed the only other alternative, practically speaking, is ether," I *may remark that on three occasions* recently I have asked the dentist to come to the patient's house and the patient being in bed I have given chloroform in the usual way. No great difficulty has in any of my cases been noticed and ample *time*—a very important matter—has thus been given to the operator. I am, Sirs, yours faithfully,
Streatham, S.W., March 30th, 1906. E. H. WORTH.

ANTERIOR OR POSTERIOR GASTRO-JEJUNOSTOMY?

To the Editors of THE LANCET.

SIRS,—Will you allow me to reply to some of Mr. B. G. A. Moynihan's kindly criticisms of my recent Hunterian lectures? *I welcome such criticism*, as it cannot but further our knowledge and aid in distinguishing between the wheat and the chaff of the various surgical procedures adopted at the present time. As I anticipated would be the case, Mr. Moynihan takes exception to the opinion expressed in favour of the anterior operation and he maintains that "every argument and all experience show that the posterior operation *as now performed* (the italics are mine) is the better operation." Mr. Moynihan, I take it, here refers to the "no-loop" method. Now, I would point out that in my lectures I expressly stated that my arguments referred to the posterior operation *as usually performed*, and, in London at any rate, the no-loop method is not yet that most commonly adopted. While pointing out that the *no-loop method involves* more manipulation and that should any fault develop at the site of the anastomosis it would be very difficult to remedy it, I avoided any dogmatic statement as to the merits of this operation on the ground that we have not yet sufficient evidence on which to s to get absolutely authentic information on this point, armed with an introduction from the Paris Municipal Council, I called on M. Albert Cuvillier, Président de la Chambre Syndicale des Négociants en Vins de Paris. The President of the Union of the Paris Wine Merchants assured me that the Potin wine, at 2½d. the litre, was excellent and quite pure, nor was there anything in the least degree surprising about this. He then took me to a great wine shed and invited me to taste several wines which, he said, contained from 9½ to 10½ per cent of alcohol and which could be delivered in the cask to grocers and others at such a price as to yield a sufficient profit to the retailer if sold to the public at 2½d. the litre. As for adulteration, it did not pay to falsify such cheap wines, though there was no accounting for the stupid and, in the present circumstances, useless manœuvres to which some people resorted. Of course, there is a good deal of *coupage*, but there is nothing unwholesome in mixing highly coloured wines with wines that have less colour or a strong wine with a weak wine to obtain a medium wine. In any case, there is no difficulty in obtaining very large quantities of absolutely pure wine at from 2d. to 3d. the litre. But would it be possible to sell this wine cheaply enough in England? Even the cheapest wine would travel very well, except, of course, in the height of summer. Going through the figures carefully, which, of course, M. Cuvillier had at hand, he said that a barrel of wine containing 225 litres, or 50 gallons, paying 77 francs 50 centimes duty, would cost when delivered in London 70 centimes a litre. That is equal, as nearly as possible, to 4d. a pint, and it should be possible to retail such wine at about 5d. a pint It would probably contain from 9 to 9 5 per cent of alcohol and therefore some water could be added and the cost of the drink reduced to about 4d. a pint, the same price as the best English ales. This would be a "hygienic drink' but not a cheap drink. There are not many persons who can afford 4d. per meal for their drink. Therefore, if we want to utilise French wines to combat alcoholism in this country, the British Government must follow the example of the French Government and abolish all taxes and duties on "hygienic drinks." Then we could have perfectly pure sound wine at five farthings a pint, or, allowing for a small addition of water, at 1d. a pint.

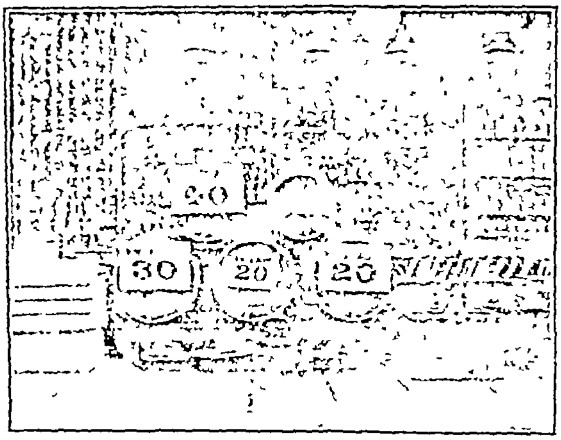
---

[1] Brit. Med. Jour., Nov. 3rd, 1894, p. 968.

Unfortunately, even if this could be done, the palate of the majority of people in this country has been so utterly spoilt by crude spirits, sophisticated wines, to say nothing of vinegar, patent sauces, strong pickles, and coarse, sodden tea, that when a thoroughly pure and natural wine is given to them they do not like it. Because it is not artificially sweetened they say it is sour, and because injurious spirits have not been added they say it is weak and thin Wine merchants, who are merchants rather than social reformers, have long ago learnt how to manufacture a wine to suit the corrupted British palate. For this purpose dry currants are employed as they contain a great deal of sugar but artificial colouring matter has to be added. This sort of wine is sold wholesale to City and other firms for mixing purposes It is not cheap. Sound genuine wine would not be dearer but it would not suit the ordinary ignorant British purchaser. The usual thing is to take half a barrel of this dry currant English-made wine which costs £1 10*s*. Then a quarter of a barrel of Spanish Rioja or Alicante wine is added which costs 15*s*. Another 15*s* are expended in the purchase of the genuine French wine which gives its name to the unholy mixture. The duty on these foreign wines will amount to £1 10*s*. and there will be 5*s*. for carriage, so that the barrel of 225 litres, or 24 dozen bottles, comes to about £4 15*s*., or 4*s*. the dozen bottles. But to this must be added the price of the bottles, the corks, the metallic capsules, the labels, and the labour, so that altogether the mixture when bottled costs the merchant 6*s* the dozen. This he will sell to the grocer for about 8*s* the dozen and it is retailed to the public as French claret at 1*s* or more a bottle. No wonder that persons who have been accustomed to drink this sort of mixture all their lives fail to appreciate a glass of genuine wine when it is given to them Should a little alcohol of commerce be added then, instead of a "hygienic drink," we have something that might easily be injurious to health. Strong measures should be taken against any such mischievous deception.

But in spite of all impediments and duties perfectly wholesome and pure wine should be as cheap now in London as it was in Paris before the abolition of the *octroi* duties. Though there were deplorable exceptions, still, the Parisians, even with comparatively dear wine, were much more sober than the inhabitants of London. The state of France during the phylloxera, deplorable as it seemed to Frenchmen, would be a great improvement on what to-day exists in England. If wine can be retailed in Paris for 2d. to 3d. the litre it can be sold in London for 8d. to 10d. the litre. At a large grocer's shop situated within a hundred yards or so of the private residence which M. Loubet has occupied since he left the Palais of the Elysées I bought a litre of wine for 2d. Then in testimony of this transaction I photographed the part of the shop where the wine was retailed. This was easy to do as the wine was placed outside the shop on the street pavement. Of course I purchased the cheapest of the wines—namely, the *vin de* [illegible]—which was drawn from the middle barrel. Had I given 3d. I could have had Algerian wine, while for 4d. I could have indulged in Bordeaux wine The litre of wine I carried with me in the heated railway carriage and the cabin of the boat. Then it had a good shaking on the Metropolitan Underground Railway and altogether my litre of wine had a varied experience of different temperatures above and below ground on land and on sea. Nevertheless, when it finally reached THE LANCET Office it was still sound and the flavour was quite palatable. Though this wine only cost 2d. the litre, or about 1¼d. the English pint, it gave perfectly normal results on analysis. It has the same composition as high-class and consequently expensive clarets. In the latter case the purchaser has to pay above all for the bouquet, then for the comparative scarcity or limit of the supply, then again for the storage in cask and afterwards in bottle extending over several years, during which time a certain portion of the wine evaporates, occasionally an accident causes some of it to "turn," and there is always the interest on the capital invested to store and watch or nurse wines. It is necessary to understand why the higher-class wines must be comparatively dear so as to realise how it is that other wines can be extremely cheap The latter have little or no bouquet. They come from vineyards that have acquired no special trade reputation; there is therefore no particular demand for such wines and the production is often greater than the sale. But these cheap wines are in every respect as healthy as the dear wines and therefore well suited to provide "hygienic drinks" to the great mass of the people In the sample purchased for 2d. the litre and brought to London the only point open to criticism is the trace of a slight intensification of colour. Probably this good wine was sold cheaply because it was somewhat deficient in colour, and had it been allowed to remain so it would have been none the worse from the hygienic point of view, though perhaps it might not have sold so readily.

FIG. 1.



A grocer's shop where wine is sold at 20 centimes the litre.

From this grocer's shop I proceeded a little way up the rue Monge and there photographed a small wineshop. Two typical market women, with their provision baskets on the ground, are sitting for rest and a gossip at the little tables placed outside on the street causeway. It may be remarked that the taking rest and refreshment in the open street or

TEMPERANCE LEGISLATION IN FRANCE.

CAN ENGLAND PROFIT BY THE FRENCH EXAMPLE?—THE DIFFICULTY OF OBTAINING "HYGIENIC DRINKS."—PURE WINE AT FIVE FARTHINGS THE PINT IN FRANCE AND FIVEPENCE IN ENGLAND.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

PART III.[1]

IT has been necessary to insist at length on what has occurred in Paris, because in no other part of the country has the abolition of *octroi* dues on "hygienic drinks" involved anything like so great a sacrifice. The *Bulletin de Statistique*, published in May, 1900, by the Minister of Finance, estimates the gross receipts of all the *octrois* in France at £13,327,700, from which are deducted £1,200,000 as cost of collection. Out of this the *octroi* of Paris takes about half—namely, £6,256,420. The *octroi* duties on wines, beer, and cider throughout France amounted to £3,466,440 and of this amount two-thirds were paid at the Paris *octrois*, where the duty on "hygienic drinks" used to be so much higher than in any other part of the country. Apart, however, from the action of the municipalities it is necessary to take into consideration the sacrifices made by the State in the cause of temperance. From the fiscal point of view there were three categories: first, wine, cider, perry, and mead; secondly, spirits, brandies, liqueurs, absinthes, and other alcoholic liquids; and thirdly, beer. The first category had to pay a tax for "the right of circulation" from one to two francs the hectolitre of wine according to the department from which the wine came and the place to which it was to be sent. For cider, perry, and mead this tax was uniformly 80 centimes. Then the right to sell retail was taxed by the State *ad valorem* 12½ per cent. of the sale price. Spirits paid a general tax of 156 francs 25 centimes per hectolitre of pure alcohol. On beer a brewing tax was imposed of 3 francs 75 centimes per hectolitre of strong beer and 1 franc 25 centimes per hectolitre of thin beer. Under the new *régime* the State, as well as the municipality, sacrifices all taxation on "hygienic drinks" except the very trivial charge made for the "right to circulate." That is to say, that on wine not drunk where it is made must be paid 1 franc 50 centimes (or 1*s*. 3*d*.) per hectolitre (or 22 gallons) for permission to send it to other parts of the country. For cider, perry, and mead this tax is only 8*d*. for 22 gallons. For brewing the tax has been reduced to 25 centimes per degree of alcohol per hectolitre, which in practice amounts to a tax of about 1*s*. for every 22 gallons. On the other hand, the State increased the general tax on spirits from 156 francs 25 centimes to 222 francs the hectolitre. In rural and all other districts this tax on spirits must be paid to the State and if spirits are sent to towns the tax is increased from 7 francs 50 centimes to 30 francs the hectolitre. In Paris, where over and above these State charges the *octroi* dues have been doubled, the total of the State and local taxes on spirits amounts to no less than 415 francs or £16 12*s*. the hectolitre or 22 gallons. In England the tax on spirits is £13 and in Russia £20 the hectolitre. By increasing the tax on spirits the annual revenues of the State have been augmented to the extent of about £400,000 and those of the city of Paris, though increased, were, as already related, £280,000 less than they would have been had the inhabitants continued to drink as much spirits as before. To the State the loss on the almost complete removal of the taxation on "hygienic drinks" has been £1,404,408, which, though considerable, is less than that experienced by the city of Paris. The State loss on cider and beer does not amount to more than about £28,000. The first year after the application of the new system it was calculated that by the abolition of the taxes on "hygienic drinks" the State lost in revenue £1,431,064. This is a good price to pay so that the people may have wholesome wine at cheap rates but it is a smaller sacrifice than that incurred by the city of Paris. At the lowest computation—that is, counting economies made in the cost of collecting and adding to this other offsets—the net loss was set down at £1,707,388. Thus, and at the lowest estimate, the city of Paris and the French nation sacrificed £3,128,452 during the first year that these reforms were applied. This is the sum paid during the course of one year so that the French people might obtain the most plentiful supply possible of "hygienic drinks" almost entirely free from taxation, whether State or local.

If the *entente municipale*, of which we have heard so much of late, is to mean anything more than a demonstration of political sympathy between the capitals of the two nations concerned, surely this bold legislative and municipal attempt to deal with the temperance question should be carefully considered on this side of the Channel. Naturally, it will suggest the question whether it is possible to place "hygienic drinks" within the reach of the British public. It is true that we are not a wine-growing country, but beer is recognised as a "hygienic drink" if properly made. Already in the House of Commons a Pure Beer Bill was recently introduced stipulating that not less than 85 per cent. of the saccharine-yielding material employed shall be barley malt, without any addition other than hops, yeast, and water. The Bill was rejected but other similar efforts will be made. If ultimately some such law is rigorously applied it might then be safe to conclude that English-made beer had become a "hygienic drink"; but would it be a cheap drink? Mr. Scott Wood, a director of Messrs. M. B. Foster and Sons, is reported by the *Tribune* to have stated to its representative that such a provision would not affect Bass's ale, "but many brewers of the cheaper table ales, 'the 2*s*. 6*d*. ales,' employ rice, grain (i.e., maize), and sugar. These brewers would find much of their plant useless under the Bill and the 2*s*. 6*d*. ales could not be profitably produced."

Of course, Munich beer, protected by laws more than 500 years old which render it a criminal offence to make beer with anything else whatsoever except barley-malt, hops, yeast, and water, may be considered an "hygienic drink." This was set forth by our investigations carried out on the spot and the minute analyses of the beer.[2] Further, Munich beer is cheap enough—in Munich. But what with duty and the cost of transport in ice it is not retailed in London at less than 5*d*. or 6*d*. the half litre and it does not contain half as much alcohol as sound French wines which can be bought in London for the same price—namely, 10*d*. to 1*s*. the litre. On the other hand, the ordinary Englishman, especially if he belongs to the working-classes, would probably take more willingly to Munich beer than to genuine French *vin ordinaire* mixed at table with about 50 per cent. of fresh water. Indeed, the idea of mixing wine with water is quite foreign to the English mind; yet it is the universal custom in France, and what a pleasant thirst quencher this provides in the hot, dry days of summer. Beer brewed in this country should be pure and cheap and no doubt such beers exist. At the same time and in the absence of any law beer is often made with glucose, which, it will be remembered, has been found to contain arsenic. The purchaser does not know what he is drinking; there is no legal guarantee of wholesomeness. The same may be said of many other countries and the one State that stands before the world as a model in this respect is Bavaria. That is why Munich beer comes to the front when mention is made of "hygienic drinks."

Now, however, that more wine is produced in France than can be sold, the question arises whether wine might not serve the purpose of a "hygienic drink" in England as well as in France. In considering this matter it will be found that there are not many people on this side of the Channel who know how very cheap wine has become. Some few years ago, and before the abolition of the *octroi* on wine, there was a specially abundant vintage. Consequently wine trains were despatched to the outskirts of Paris and there shunted on sidings. The people were invited to come with all the pitchers and pots and pans that they could find and to buy wine contained in the great iron tanks carried by the train. The price was 15 centimes the litre—that is, less than a penny a pint. Now to-day that the *octroi* on wine is abolished, and even when the vintages are not so very plentiful, wine can be purchased within the walls of Paris at 20 centimes or 2*d*. the litre. This is certainly the lowest price and the majority of people pay more. But a well-known grocer, whose shops are in all parts of Paris and who is especially patronised by the British colony, Felix Potin, offers in his price list red wine "guaranteed pure" at 25 centimes the litre. This firm claims to sell 60,000 litres or bottles of wine per day. So great interest in the problem. Both authorities were agreed upon the importance of rendering the houses in the central parts of the city as habitable as possible, but Dr. Robertson appears to look upon this matter as only a temporary expedient to tide over the difficulty until the time when suburban extension will relieve the present central congestion. What can be done, and is being done, was shown by Mr. Nettlefold by a series of lantern slides, and the changes for the better as regards light and air, which can be obtained in blocked courts by the removal of obstructing blocks and by re-arrangement, are most remarkable, whilst the reduction of the death-rate in the places already dealt with is most convincing as regards the value of the work on the general health of the city. The difficulties in the way of alterations and reforms are the rights of the property owners, the necessarily increased rental which the improved buildings command, and the dirty and careless habits of many of the lowest classes who inhabit the poorest houses. Gradually, however, all these difficulties are being overcome in the central areas, but if care is not taken and if the city does not obtain power to control and to supervise building in the suburbs it is most probable that conditions will arise there in the future which will be quite as bad as those now existing in the central areas. There can be no doubt that as regards the control of suburban building we are by no means so advanced as the cities and towns of Germany. Nor do we take care that sufficient space is retained for breathing purposes. With carefully thought out plans the necessary arrangement of the new buildings and the proper amount of vacant space could be secured at comparatively little cost, as Mr. Nettlefold pointed out, if arrangements are made before the property is ripe for building, but, unfortunately, as a rule we think little or nothing about the matter until the price of the land becomes prohibitive.

Child Life on Canals.

Hitherto very little attention has been paid to the children reared upon canal boats. Their health and welfare, however, are, or should be, of considerable interest to health and education committees. The Acts and regulations regarding canal boats are strictly enforced, yet the conditions of life and education are distinctly deficient when contrasted with those enjoyed by other sections of the community. This has been recently demonstrated so far as the boats associated with Birmingham are concerned, and it is to be presumed that the conditions are similar in other places, through an investigation carried out by Dr. J. D McCrindle, the assistant medical officer of health, and by Mr. J. H. Broscomb, district inspector of schools. The living quarters in the boats are necessarily confined, but in spite of the fact that the air space is only 70 cubic feet per person as contrasted with 225 required in lodging houses, the physique and general health of the children examined did not appear to have suffered as contrasted with children of the same class in the poorer parts of the town. On the other hand, their education was deplorably deficient. Only 3 per cent. could read fairly well. Many did not know the value of any but bronze coins, few could write, and their knowledge of numbers was very small. The few that had any educational equipment lived entirely ashore for a continuous period and apparently, if it is thought advisable that this class should be further educated, it will be necessary to obtain power to make the parents let the children live ashore for a certain period. Under present conditions, as the annual number of attendances the canal boat children make at school shows, it is quite impossible for them to acquire that amount of knowledge which it is generally thought every child is entitled to. Dr. McCrindle found it extremely difficult to get information regarding the deaths of children. In 19 boats no information at all could be obtained; from the other 40 which he examined he ascertained that apparently 70 per cent. survive and that the deaths which occur are due to diarrhœa and wasting diseases.

April 3rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Ladies' Charity and Lying-in Hospital.

THE number of patients attended in the outdoor department last year was 1847, as against 1900 in the year 1904. The number of patients attended in the hospital was 322, as against 281 in the previous year. 11 of these were single girls (first cases only being received) admitted by the ladies' committee for treatment after investigation had shown them to be deserving of consideration. In the school of midwifery 63 pupils were trained during the year. 21 medical students took their midwifery practice with the charity during the year in accordance with arrangements with the University of Liverpool. This showed a considerable increase and the board was pleased to note that its arrangements were meeting the needs of Liverpool students.

University of Liverpool: Graduation Ceremony; University Prizes.

The following students in the faculty of medicine were admitted on March 27th by the Vice-Chancellor to degrees: Doctor of Medicine, Hubert Gordon Thompson; Bachelor of Medicine and Bachelor of Surgery, Austin William Byrne and James M'Clellan. The following awards are also announced: University Scholarship in Medicine, Thomas William Jones; Derby exhibition in clinical surgery, Robert A. Hendry; Torr gold medal for anatomy, Ethel M. Baker; Holt medal for physiology, Thomas William Jones; and Gee prize for diseases of children, George C. Barnes.

The Health Committee and Chicken-pox.

In consequence of the cessation of cases of small-pox in Liverpool the health committee has issued a notice to the local members of the profession that chicken-pox has been removed from the schedule of notifiable diseases.

Donation to the David Lewis Northern Hospital and the Royal Southern Hospital.

The treasurers of the David Lewis Northern Hospital and the Royal Southern Hospital acknowledge with thanks the receipt of £2350 each from Mr. John Elliott (the trustee), being the proportion of the estate of the late Mr. C. H. Lear assigned to the two hospitals for investment.

Extension of Warrington Infirmary.

Plans have been prepared for the erection of a new pavilion with three wards to accommodate 66 extra beds. The scheme, which was adopted by the governors, will cost between £10,000 and £12,000. Mr. W. Long of Grappenhall has sent a donation of £1000 towards the extension.

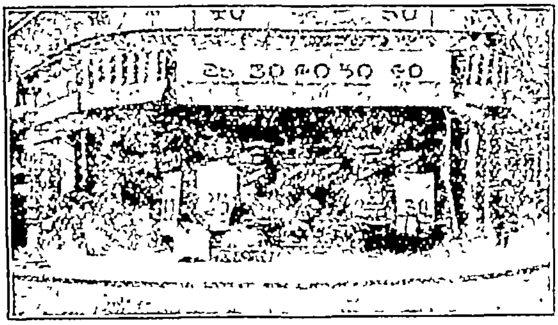
St. Helens Health Committee and Consumptive Patients: Decision of the Committee.

At a meeting of the St. Helens health committee held on March 23th a lengthy report was submitted by Dr. J. J. Buchan, the medical officer of health, on the inquiries he had made as to the manner of isolating consumptive patients in the vacant wards of the fever hospitals at Manchester, Edinburgh, and Brighton, reference to which was made in THE LANCET of March 24th, p. 863. At Manchester the patients were being treated in cottages near the hospital. Dr. Buchan gave details of cases recently reported to him which urgently called for isolation. The chairman moved that the medical officer of health be empowered to admit cases to the sanatorium on the same lines as fever patients were admitted and that all cases be reconsidered every month, when it could be determined whether to retain or to discharge them. The motion was adopted. The question was mooted whether cases should be admitted to the hospital in advanced or early stages. Dr. Buchan considered that he should not be tied to any hard-and-fast rule. Mr. H. B. Bates considered that the advanced cases, being the most infectious, should have the preference in order to prevent the spread of infection. The matter can be safely left to the medical officer's judgment.

Blackpool Sanatorium: Reopening after Enlargement.

The Blackpool Sanatorium was reopened on March 26th after enlargements which have cost about £18,500. Though the institution is still incomplete there is now accommodation for 54 beds and eight cots. When the whole scheme is completed, including another large block for 22 beds and a discharge block and porter's lodge, estimated to cost about £6500 more, the total cost, including land, buildings, furnishing, &c., will have been about £33,900, the cost per bed working out at about £424. There will then be room for 76 beds and eight cots. Dr. F. J. H. Coutts, the medical officer, in his comments on the extensions, says that they will very materially improve the conditions as to hospital treatment of infectious diseases. It will enable them to give a much larger air space for each patient than had hitherto been possible. He adds that it has been a matter behind glass windows indoors but still in view of all persons passing in the street, is a great guarantee for the maintenance of decent behaviour and sobriety. Here it will be seen by the posters and other announcements that wine is retailed at 25 centimes or 2½*d.* the litre and old wine (*vin vieux*) at 3*d.* the litre. Above there are announcements of various wines from 2½*d.* to 5*d* the litre.

FIG. 2.



Wine shop and café, rue Monge.

In London the cheapest wine that I have been able to find is sold at 7½*d.* the litre. On analysis this wine does not appear to have been imported. In all probability it has been made in London, possibly from dried currants and also from the juice of grapes, pasteurised and then imported in an unfermented condition, so that there should be no duty charged.

Finally, I endeavoured to obtain not the cheapest but a really sound and genuine wine. For this purpose I sought out a French grocer, a refugee of the Paris Commune, whose shop, since the dark days of 1871, has been a centre for French political exiles. These poor men and women have for the greater part been accustomed from their childhood to the cheap natural wines that are such effective factors in maintaining the sobriety for which the wine-drinking sections of the French people have acquired a just and honourable reputation. In a quest such as mine it was absolutely essential to avoid dealers having English customers and an English reputation. A wine that has a ready sale among ordinary English purchasers must be looked upon with the gravest suspicion. The thing is to find out where poor French people buy their wine; and even this does not suffice, for they must be from the centre or south of France. Acting upon this principle I found two wines from the Bordeaux districts of Blaye and Bourge, where the cheaper wines or *vins ordinaires* of the Bordeaux *cru* are made. The former has a more emphatic flavour, while the latter is more delicate. Both leave in the mouth that clean fresh sensation typical of a light natural wine. There is nothing thick, treacle like, heavy, or rough about such wines. It is the difference between muddy water and clear fresh water from a spring. On analysis the sample of the Bourge wine proved to be a genuine wine. In regard to the colour, the proportion of alcohol, which is 12·49 per cent. by volume, the nitrogenous substances, tannin, sugar, and the other ingredients all go to show that it is a pure, natural, wholesome wine. Here, then, is all that can be desired from the health point of view, if only the price were such as to place it within reach of the masses. As matters now stand it can only claim to be a "hygienic drink" suitable for the more prosperous artisan and the lower middle-classes. It is still too dear for the labouring and very poor classes who supply, in spite of their poverty, so large a proportion of the victims of alcoholism. But this wine would be in reach even of those classes if in England, as in France, all duties were removed from "hygienic drinks." At present this wine costs 10½*d.* the litre. This is equal to 6*d.* the English pint. But seeing that the proportion of alcohol is rather high this wine might, for drinking at meals, stand an addition of a quarter to a third of its volume of water and thus a very wholesome and pleasant drink could be obtained at 4*d.* or 4½*d.* the pint. Of course, these are retail prices, the wine being bought a litre at a time over the counter. Naturally a wholesale transaction would be cheaper.

Thus it will be seen that though the duty paid on wine is often much in excess of the price of the wine, still wine is now so cheap that it is available even in this country at a moderate cost. Therefore the temperance experiment which the French Government and municipalities have made on so extensive a scale could be attempted in England. Those sections of the community that are not absolutely poverty-stricken and are sufficiently intelligent to profit by the great object lesson we are now receiving from the other side of the Channel might endeavour to solve the temperance problem on these lines. The *entente cordiale* and the *entente municipale* will not be vain words if they serve to promote in England a knowledge of the fact that the evils of drink arise largely from the unwholesome nature of the drink. Given "hygienic drinks" these evils would be reduced to a minimum as is actually the case in those favoured wine-growing countries where pure wine is so abundant that dangerous spirits and unwholesome beverages are rarely consumed.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday.

THE annual report of the Birmingham Hospital Saturday Committee is a record of good work well done. It proves conclusively that the scheme has secured the goodwill and coöperation of all classes in the city. The working classes are particularly to be congratulated upon the aid which they have given to an institution which does so much for their members in times of trouble and distress. The collections for the year amounted to £18.722, or £200 more than any previous yearly collection. The contributors have increased in number, more patients have been sent to convalescent homes, and the expense per patient has been reduced. Birmingham has every cause to be proud both of its Hospital Saturday Committee and of the amount that the committee has collected for the prosecution of the good work in which it is engaged.

The City Analyst's Report.

On the whole the report of the city analyst for the past year is satisfactory. There appears to have been a general diminution in the adulteration of foods except butter. Whether this is due to an increase of morality or a greater fear of punishment does not matter to the general public, who will be chiefly interested to know that the greater part of their food, and their milk in particular, is less tampered with than in the past. The fact that butter has been dear seems to have increased the tendency to fraud and of the 239 samples taken 23 were adulterated. In the ordinary course of events the added adulterants are frequently preservatives but 10·5 per cent. of the samples taken last year were adulterated in other ways and for the purpose of increasing the gain of the seller. An extremely interesting part of the report refers to the new water-supply. Our old supply contained from 30 to 40 parts per 100,000 of solid matter but the Welsh water only contains from 5·8 to 7·2 parts, of which about half is hardness. There was for a time some fear that the soft water would dissolve a dangerous amount of lead from the supply pipes. A careful investigation has shown that when the water has been standing in the pipes all night, and especially if the pipes are new, small quantities of lead can be detected, but the analyst is satisfied that there is no danger to health if the first quart or two drawn in the morning are allowed to run away. It should not be forgotten, however, that galvanised iron kettles yield a dangerous amount of zinc to some waters and that if kettles lined with tin are used care must be taken that the tin contains no lead, otherwise poisoning may result. Latterly a small amount of chalk has been added to the water and the hardness of the water has thus been slightly increased, but it still remains very soft and its colour has been less brown. It is interesting to note in association with the softness of the water that one of our public companies has acknowledged a saving of £100 a year on its soap expenses since the new water-supply was established.

The Housing Problem.

Within a fortnight we have had two interesting and extremely instructive lectures on the housing question, one delivered at the University by Dr. J. Robertson, the medical officer of health, and the other given to a very large audience at the town hall by Mr. J. S. Nettlefold, a member of the housing committee of the city council, who has taken the purpose. Dr. Cullen seconded the recommendations and pointed out that 80 per cent. of the deaths had occurred in houses under £20 rental and held that their plain and pressing duty was to provide the accommodation recommended. Dr. Robertson also supported the proposal. Some criticism and opposition were offered by several of the members but were ultimately withdrawn and the recommendations of the public health committee were unanimously agreed to.

Edinburgh Church of Scotland Deaconess Hospital.

At the eleventh annual meeting of the supporters and friends of this hospital it was stated that during the past year there had been 415 patients received, as compared with 341 the previous year. The death-rate had been 4·7 per cent. The district nurses had visited 594 cases. The expenditure for the year was £1808, making the expenditure per bed £57 6s. 8d. The income was, for the first time, not equal to the expenditure. In supporting the report Dr. J. Playfair, President of the Royal College of Physicians of Edinburgh, spoke of the good work which the hospital was doing and thought that compared with the cost of other hospitals they were getting good value for their money.

Professor Sims Woodhead in Glasgow.

Recently Professor G. Sims Woodhead visited Glasgow in his capacity as President of the Temperance Collegiate Association and addressed several large meetings on the subject of Alcohol and Disease. In his honour a banquet was given by the Lord Provost and health committee of the city, a large proportion of those present being medical men.

Vaccination in the Eye.

An unfortunate accident has happened to a medical man in practice in Greenock. While breaking a tube of vaccine lymph a splinter of glass entered his eye which in a few days exhibited the usual signs of successful vaccination. It is probable that the resulting impairment of vision would have been more serious but for the fact of his having been revaccinated two years ago.

Lane Lecturer at San Francisco.

Dr. J. C. McVail, the medical officer of health of the counties of Dumbarton and Stirling, has received and accepted an invitation to be the next Lane lecturer in the Cooper Medical College, San Francisco. This lectureship was founded some ten years ago, the first lecturer being Sir William Macewen, and since then several eminent British medical men have been similarly honoured. The course consists of ten lectures in the month of August and they are largely attended not only by the medical men of San Francisco but also by the general public. Dr. McVail's subject will be "Hygiene." The county councils of Stirling and Dumbarton have readily consented to allow Dr. McVail the necessary leave of absence.

April 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of William Logan, M.D. St. And., M.R.C.S. Eng.

I REGRET to report the death of Dr. W. Logan which took place at his residence Knocknagulla, Whitehead, co. Antrim, on March 25th, in his seventy-first year. The deceased gentleman was a native of Straidnahanna, near Carrickfergus. In his early life he studied at Queen's College, Belfast, for the medical profession and graduated in 1862 M.D. of St. Andrews; in the same year he became M.R.C.S. Eng. For many years he practised in Belfast and afterwards in Yorkshire, where his arduous duties so undermined his health that he had to retire from practice and to return to Ireland, where he lived near Whitehead. Dr. Logan is survived by his widow and he leaves two sons and a daughter, all three being members of the medical profession.

Royal Victoria Hospital, Belfast.

At the annual meeting of the friends of this institution held on March 28th a very satisfactory report and financial statement were submitted. As to patients, 2638 new intern and 25 917 extern cases were treated, and 1117 surgical operations were performed with a 4·4 per cent. mortality. Patients are arriving in increasing numbers from all parts of the north of Ireland for surgical treatment. Financially, the net receipts from all sources were £14,877 11s. 7d. and the disbursements of all kinds amounted to £14,735 0s. 1d., leaving a small surplus as balance of £142 11s. 6d. The chairman (Mr. R. H. Reade, D.L.) spoke of the singular comfort and cheerfulness of the wards and of the plenum system of ventilation, which had answered its purpose admirably. By it "they had," he said, "been able to obtain a fresh current of air without any draughts, the temperature had been maintained at the desired point, and, further, there was an advantage not anticipated—namely, that they had been absolutely free from flies in the summer-time." It is interesting to know that the cost of the patients has been only 2s. 2½d. per day during the past year, or 6d. less than in the preceding one; in 1903 the time spent in hospital was, on an average, 26 days; in 1905 it was 24½ days. Dr. H. L. McKisack (secretary of the medical staff), on behalf of his colleagues, said that they had every reason to be satisfied with the administration of the hospital. They hoped the additional four wards would soon be opened.

Tughan v. Darnell.

A joint meeting of the Ulster branch of the British Medical Association and the Ulster Medical Society was held in the Medical Institute, Belfast, on March 29th. Dr. W. Calwell occupied the chair and there was a very large attendance of the members of the medical profession. Sincere sympathy was expressed in reference to the result of the action with Mr. C. K. Darnell. After a long discussion it was decided to take the opinion of counsel as to the effect of the law on the medical profession as it was interpreted by the judge in the case, Chief Baron Palles. I understand that a meeting of the profession will be called later; in the meantime notice of appeal has been given.

Action by a Nurse against a Medical Man.

Mrs. Harvey, a midwife, brought an action for slander against Mr. Richard Dalton, a physician practising in Cork. The case came on for hearing on March 24th before the Lord Chief Justice, and the court was crowded. Mrs. Harvey usually takes what are called "running cases"—that is to say, she might attend several women in labour in the one week. She attended a Mrs. Donovan and some time afterwards Mr. Dalton was called in to see the baby. The nurse stated that she was present on the occasion of his visit and that he informed her that the child was "rotten with syphilis." In further evidence she said that having heard rumours that she had conveyed contagion from a case of puerperal fever to the infant she, accompanied by her mother who is also a midwife, called on Mr. Dalton who then told them that the child was suffering from cellulitis and they asked him why he had changed his diagnosis in the meantime. Describing the condition of the child on the occasion of Mr. Dalton's first visit she stated that the umbilicus was quite healed. Mr. Dalton in his evidence denied positively that he had ever stated the child had syphilis and added that it was from the nurse herself the suggestion came; that she had said to him that the illness of the child was due to the condition of the father's blood. He swore that he never treated the child for syphilis, as it was from omphalitis and spreading cellulitis that the little patient was suffering and that he had registered the death as being due to spreading cellulitis. In the course of further evidence it appeared that Mrs. Harvey, some days after she had delivered Mrs. Donovan, attended a Mrs. O'Neill who developed puerperal fever, was removed to the workhouse hospital, and died there. The nurse swore that when in attendance on Mrs. O'Neill she was not aware that she was suffering from puerperal fever, that she delivered several other women soon afterwards, and that all of them recovered without exhibiting any abnormal symptoms. It further came out in evidence that the father of the child Donovan, who was very indignant on hearing the rumour that he had transmitted syphilis to his child, put the sanitary authorities in motion, with the result that the corporation van arrived at the nurse's residence for the purpose of removing her clothes for disinfection. The case was at hearing during the whole day and the judge, when addressing the jury, charged markedly in favour of the plaintiff. The jury retired and after about an hour's deliberation brought in a verdict for the defendant and judgment was marked accordingly. As the evidence was so contradictory many considered that the task of the jury was a difficult one, but it now turns out that they did not discuss the question of veracity, as they came to the conclusion that the communication made by the defendant to the plaintiff in the presence of her mother was privileged. It is interesting to note that the judge in the of great regret to him during the past few years that over and over again he had to refuse to take in cases of diphtheria, frequently with the result of extension cases occurring. The possibility of isolating doubtful cases for a few days would also be a great gain, and there would also be the advantage of isolating cases of mixed infection, the want of which had often caused much embarrassment in the past. The formal ceremony of inauguration was performed by Alderman T. H. Smith, the chairman of the health committee.

April 3rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Typhoid Fever at Bridgend.

TYPHOID fever has been endemic in Bridgend for many years past and although the medical officer of health (Mr. Wyndham Randall) has frequently urged upon the urban district council the importance of appointing a sanitary inspector who should give his whole time to the duties of his office the council for a long time was satisfied with adding the inspector's duties to those of the town surveyor. After the serious outbreak of last year, however, an officer was appointed as assistant inspector and his principal duties were to be the testing of the house drains in the town. By means of the smoke test he found during 12 months 224 defective drains and it might have been supposed that the discovery alone of this large number would have been sufficient reason for continuing his services. It is to be regretted, therefore, that the district council should have decided to dispense with the services of this special officer and to revert to the former system combining the offices of surveyor and inspector of nuisances. It is true that instructions have been given to the surveyor to devote two days each week to the work of testing house drains, but even then it must take three years to carry out the same amount of work which has been performed in the past 12 months by a man wholly employed in it. It is due to the inhabitants of the town to say that the retrograde action of the district council is not supported by the local press or by the medical profession. It is pleasing too to find that the local branch of the Amalgamated Society of Railway Servants has strongly urged upon the council the desirability of continuing the systematic inspections of the past year.

Health Report of Bath.

The annual report of the medical officer of health of Bath (Dr. W. H. Symons) is of interest as showing a steady decline in the birth-rate during the past 40 years. In 1867 it was 25·7 per 1000 of the population and in 1905 it was 19·7 per 1000. But Dr. Symons very properly points out that in comparing the birth-rate in Bath with that of the rest of England and Wales it is necessary to make certain corrections, for in Bath there are only 95 young married women per 1000 of the population, while in the rest of the country there are 117 per 1000. The corrected birth-rate in Bath in 1905 was thus 24·2 per 1000. After making this correction the fall in the Bath birth-rate is seen to anticipate the fall in the birth-rate in England and Wales by about ten years. In 1881 the corrected birth-rate in Bath was about equal to that recorded in England and Wales in 1891 and the rate for Bath as corrected was 26·7 in 1895, the rate in rural England in 1905 being 26·8, and in the whole country 27·2 per 1000. The sanitary department of the city of Bath has been much improved under Dr. Symons's administration. One of the most important innovations due to his initiative is the method of receiving notice of and tabulating deaths. Copies of death certificates are sent to him on cards provided for the purpose within 24 hours of registration, so that prompt inquiry may be made and rooms disinfected before they are taken into use after deaths have occurred. A separate card is used for each death, so that tabulation is facilitated with a minimum of clerical work. The concluding remarks in this report ought to be brought under the notice of those who are prone to criticise the work of sanitary officials. The duties of a medical officer of health, says Dr. Symons, bring him into conflict with many private interests and great responsibility attaches to most of his actions. The tendency is to give such an officer the maximum of responsibility with the minimum of control; to be successful he must be quick to think out a problem to the end but slow to speak. Success in preventing disease necessarily attracts no notice, but a failure, a single false step, a thoughtless remark, or perhaps a mishap which he could not prevent, is patent to everyone.

The Colston Society.

The annual banquet of the Colston Society in connexion with University College, Bristol, was held on March 30th. The President (Mr. J. Arrowsmith) announced that he had received promises of £30,000 towards £150,000 required for the foundation of a Bristol university. The guests of the evening were the American Ambassador (the Hon. Whitelaw Reid) and the Right Hon. Augustine Birrell. Lord Strathcona, who was unable to be present, sent a cheque for £500 to the funds of the society. Sir William Selby Church, the new President, in a brief speech acknowledged his election.

Shell-fish and Enteric Fever.

Principally at the instigation of the Torquay corporation the Devon county council has decided to apply for powers to deal with the river Teign under the Rivers Pollution Prevention Act on the ground that cases of enteric fever have been traced to the consumption of sewage-contaminated cockles taken from the estuary of the river. The Teignmouth urban council and Newton Abbot rural district council have decided to petition the Local Government Board not to comply with the application owing to the heavy expenditure that would be required to prevent the discharge of the sewage of Bishopsteignton, Teignmouth, and other places into the river.

The Yeovil Board of Guardians and Vaccination.

At a meeting of the Yeovil board of guardians held on March 24th, a member submitted a motion in favour of the abolition of compulsory vaccination, remarking that the present law was absolutely without justification and the practice of vaccination cruel and loathsome. In opposing the motion a member stated that the medical profession were practically all in favour of vaccination which showed that it was manifestly of advantage to the country. The chairman said that if there was nothing in vaccination it was surprising that foreign nations should have adopted it. There was a long discussion and on a division three voted for the motion and 29 against.

April 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Town Council and Pulmonary Tuberculosis.

A SPECIAL meeting of the Edinburgh town council was held on March 27th for the purpose of considering a report by the public health committee recommending that temporary accommodation should be provided at the city hospital for 50 advanced cases of pulmonary tuberculosis. Mr. Gibson, the convener of the committee, submitted the report. He said that the committee had come to the conclusion that there was a plain duty incumbent upon the town council to devise means to deal with cases in the last stages of the disease which were to be found in houses of inadequate accommodation. The cost of providing for 50 such cases was estimated at £1000 per annum. The result of such action as was advised would be the immediate abstraction of 50 sources of dangerous infection. The experience of a similar institution in Paris was that the average life of such patients was three months and on that basis they would deal with 400 cases per annum, but if only half that number was dealt with there would be a large reduction of dangerous risk. Since 1898 the public health committee had been:—1. Inquiring into the mortality from tuberculosis. 2. Distributing leaflets directing attention to the need of fresh air, to the necessity of destroying the expectoration from infected persons, to the thorough disinfection of bedding and body clothes, to the fixing of notices on lamp-posts requesting people not to spit on the pavements, and to the notification of cases. The local authority was now invited to approve of the proposal that provision should be made in the city hospital for the most dangerous cases. Last year there had been about 500 deaths from tuberculosis and in only 210 had the offer of the committee to disinfect the houses been taken advantage of. As regarded the notification of the disease, he thought that at no distant date the council would accept compulsory notification as a necessity and as a distinct advantage. He proposed that ward 5 in the city hospital and one cottage should be used for

Diseases held its annual meeting on March 11th in Berlin, Professor Neisser of Breslau being in the chair. Dr. Blaschko, the general secretary, reported that the association had now 5000 members and included 22 local committees; 1,500,000 copies of the pamphlets or leaflets published by the association had been distributed to the public. He also said that the newspapers now permitted subjects of this kind to be discussed in their columns and that there were only a few places where the work of the association was opposed by false prudery. After the inaugural business had been transacted a question relative to clubs under the Workmen's Insurance Laws was discussed. The principal sick clubs had on several occasions sent delegates to hygienic congresses, but one of the law courts had recently decided that it was illegal for these clubs to use their funds in paying the expenses of the delegates. As it is highly desirable from a hygienic point of view that representatives of the working classes should continue to take part in this and other hygienic congresses a motion was adopted requesting the Government to amend the legislation on that subject. The association then discussed the statistics of venereal diseases and adopted a motion to the effect that a collective investigation concerning the spread of these diseases should be carried out under the control of the Government medical department. Medical practitioners and the hospitals would be invited to take part in the investigation which would, of course, be strictly confidential. Dr. Blaschko then drew the attention of the association to a point raised in the Prussian Diet where Dr. Münsterberg, a medical member of the House, had adverted to the laws concerning prostitution. He had suggested the appointment of an extra parliamentary commission for the purpose of discussing this question and recommending alterations of the laws at present in force which were quite inefficacious. The Minister of the Interior had agreed with Dr. Münsterberg and Dr. Blaschko wished that the association should also be invited to send delegates to the Government commission. He said that two parties of essentially divergent views—namely, those who were opposed to any control of prostitution and those who were in favour of such a control—were both represented in the association and that they had been able to coöperate notwithstanding their differences of opinion. A motion, proposed by Dr. Blaschko, was adopted to the effect that the association desired an amendment of the laws and regulations concerning prostitution and that it was advisable that delegates of the association, men and women, should take part in the work of the extra-parliamentary commission appointed by the Government.

April 2nd.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Normal School for Girls in Cairo.

TEN years ago the census taken in Egypt showed that of the female population more than 99 per cent. were unable to read or to write. Since then encouragement has been given to parents to send their girls as well as boys to the elementary schools called "kuttab" and this they seem quite willing to do The normal school, now in its third year, is for 40 boarders, all Mohammedans of the poorer class, who during two years are trained to become teachers of the kuttabs for girls They vary in age from 12 to 18 years and are taught by a competent Corsican lady and several native assistants. On being drafted from the kuttabs they already know the rudiments of reading and writing Arabic and can recite by heart passages from the Koran. They are made proficient in these subjects and are also taught arithmetic, geography, history, gardening, cooking, laundry work, and ironing. They learn the theory and practice of teaching by means of a special kuttab of 90 girls, aged from six to ten years, who go every day to the normal school to be taught. They are given a free lunch, consisting of bread, lentils, and vegetables, with meat twice a week, all cooked by the pupil teachers. A playground is attached to the school, where skipping seems to be the favourite pastime. At the end of the two years' training the girls undergo an examination and are appointed as teachers or assistant teachers in the kuttabs under the supervision of the education department. This is the [illegible] that any serious effort has been made in Egypt to give instruction to the girls of the poorer folk. I was much [illegible] general air of health and cleanliness among the teachers and the taught, who are visited daily by Miss C. B. S. Amos, M.B. Lond., who has lately been appointed medical inspector of all the girls' schools belonging to the Egyptian Government. The building in which this school is situated in Bulak awakens memories in an old resident. 30 years ago it was the only lunatic asylum in Egypt, notorious for ill-treatment, starvation, heavy chains, and flogging. Then when the hapless lunatics had been moved to their present quarters in the desert it became a prison for females and a temporary nucleus of malaria. Then it was renovated, the breeding places of mosquitoes were destroyed, and it was opened as the first reformatory for boys. When the law courts discovered its existence and filled it with young thieves it had again to be abandoned and is now the happy home of many bright eyed maidens. 13 of the existing teachers in the elementary schools have been trained in this normal school.

Central Sanitary Board for the Soudan.

Sir R. Wingate, the Governor-General of the Soudan, approved last October the establishment of a new board to advise the Soudan Government on general medical and sanitary questions, including the treatment of epidemics. The president is Colonel G. D. Hunter, D.S.O., R.A.M.C., and the members are eight in number, including the director of the Soudan Medical Department (Dr. J. B. Christopherson), the medical officer of health of Khartoum (Dr. A. Balfour), three medical officers of the Egyptian army, and a sanitary engineer. This is a great advance, for the board will have to examine all schemes for medical and sanitary development, besides all legal ordinances and budgetary proposals connected with the public health.

Sleeping Sickness.

It is believed that this disease is not likely to occur in Egypt but the Egyptian Government has voted a sum of £1000 towards the cost of the programme proposed by the Royal Society for work in the direction of Uganda and will probably continue this grant for two more years.

Prevention of Tuberculosis among Government Employees.

AN important order has been issued by direction of President Roosevelt, the object of which is to protect Government employees from tuberculosis. The order is based on the report and recommendations of a committee appointed to inquire as to the dangers of tuberculosis in Government offices. The President's order directs the surgeon-generals of the Army, Navy, and Public Health Service to cause an immediate inspection to be made of the public buildings and workshops under their respective departments, and to report all insanitary conditions immediately remedial, and all insanitary conditions requiring structural changes. The public buildings not in these departments are to be inspected in like manner under the direction of the surgeon general of the Public Health Service. The order further provides that whenever there is a doubt with regard to any person in the Government service as to whether the said person is affected with pulmonary tuberculosis an order shall be issued for the said person to present himself (or herself) at one of the Government laboratories for examination and to present to the department, from the director or other authorised officer of the said laboratory, a certificate showing the result of the said examination. Having obtained the names of all persons affected with tuberculosis in any department the head of the said department shall present to each person so affected the rules prescribed by the committee for their observance. The non-observance of such rules by the employee shall, in the discretion of the head of the department, be considered as a just cause for separation from the service. It is also made the duty of the head of each executive department at Washington to cause to be transmitted to all the federal buildings under his control the rules prepared by the committee to prevent the spread of tuberculosis in the buildings [illegible] their display by the custodian in such manner and in such number as is necessary to carry out the course of his charge informed the jury that according to law a statement could be malicious though the person uttering it entertained no ill-will. The following day another action for slander by the same nurse against the father of the child Donovan was at hearing before Mr. Justice Johnson, the other judge of assize. The defendant in the course of his evidence stated that in notifying the sanitary authorities he was influenced by the desire to prevent other people from suffering as he had suffered. The jury that tried the case brought in a verdict in his favour. The nurse had an action for slander against a third party, also in connexion with the death of the child Donovan, but counsel of both sides asked for a postponement till next assizes and the judge ruled accordingly.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of Contagious Diseases in Bathing Resorts.

AT a meeting of the Academy of Medicine held on March 20th M. de Rance called attention to the fact that the danger of the propagation of contagious diseases is much less in villages, where the population is more or less scattered, than in the urban mineral water resorts, where at the height of the season there is decided overcrowding in some hotels at certain periods of the year. The aggregation of individuals and the special predisposition to further illness which exists among persons who are already in bad health, weakened, or depressed, are also favourable to the transmission and propagation of disease. Moreover, if such transmission of disease cannot be prevented and an epidemic is threatening the result may be a panic which will empty the hotels and villas. Interests which deserve consideration are therefore at stake. The medical man ought accordingly to place the patient in the best conditions for recovery, ought to take all necessary measures for preventing infection, and in the general interest ought to allay public apprehension. If there is no isolation hospital reserved for contagious diseases the patient might be removed to a house or villa fulfilling the conditions necessary for isolation and disinfection. Sometimes, however, a patient had to be kept in an hotel and prophylactic measures, no matter how carefully designed, were a failure. For the efficient carrying out of such measures it would be necessary, in the first place, to confer the requisite authority on the medical man and the mayor of the district and, secondly, to place at their disposal a building where strict isolation and disinfection could be enforced.

Action of the Extract of Cotton Seed on Human Milk.

At the same meeting of the Academy of Medicine M. Gilbert communicated a paper by M. Barlerin on the chemical modifications presented by human milk under the influence of extract of cotton seed. M. Barlerin administered the extract to women who attended the Belleville dispensary and were about to wean their infants on account of their milk being deficient both in quantity and in quality. Among all these women in from two to eight days after taking the extract M. Barlerin found an improvement in the quality of the milk. This improvement had reference chiefly to the proportion of the fatty and albuminoid constituents; the amount of fat contained in the milk increased on an average by 18 grammes per litre, or 50 per cent. of the quantity existing before the experiment. The casein increased on an average by from five to seven grammes per litre, or 48 per cent. of the previous proportion. From these experiments it therefore seems that the administration of small quantities of extract of cotton seed to women who are giving milk brings about a considerable increase of the fat and casein in the milk. This discovery may have important consequences. All medical men are unanimous in the opinion that artificial feeding is one of the causes of the considerable infant mortality which prevails in France, and especially in some of the large towns. Extract of cotton seed may therefore in the majority of cases render maternal suckling possible. It must, however, be remembered, on the one hand, that milk which is deficient in fat and casein does not adequately nourish the infant, while, on the other hand, milk which is too rich in casein, and especially in fat, is no less objectionable on account of its liability to produce gastric and intestinal derangement. Extract of cotton seed seems to be an active subst therefore ought not to be used unadvisedly. The man ought always to watch its effects, to reg administration according to the weight and stat child, and to stop it when the object in view attained.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Infant Life Protection.

AN exhibition dealing with the question of in protection has been lately opened in Berlin ur management of a committee including medical philanthropists. The care of infants is a subject interest at the present time, especially in Berlin, v enormous mortality prevails among the infants of th classes. The researches of Professor Behring on tl mission of tuberculosis by food, the endeavours wh been made to provide the infants with pure milk, a topics which have been discussed in the newspap fixed the attention of the general public on the The exhibition is therefore of a popular as we scientific character and has for its object the tion of the public, and especially young mothers, upbringing of infants. The exhibition includes partments, the first of which is devoted to statis displays statistical tables compiled by the Imperial Office and the statistical offices of several towns the mortality of infants and the dependence of this n on food, climate, the prevalence of tuberculosis, &c second department deals with the development a diseases of infants. Graphic curves showing the w children reared on natural and on artificial food tively, anatomical specimens, &c., may be seen her third department is concerned with the physiolo pathology of nutrition. Chemical researches on hum and on that of the lower animals, specimens of the present in milk, and descriptions of the met milking are the principal objects of this departmen fourth department gives details of the official work d the health of infants, such as the providing of disp and homes for them, the examination of milk a control of its sale by the authorities, model cow hou Much apparatus and many appliances for the steri and the transport of milk and for the supply of it larger cities are striking features of this departmen fifth department has for its subject the care of inf families; it contains model nurseries with beds, milk sterilising instruments for private use, &c. The six last department deals with the care and supervi foster-children and the control of the foster-parents authorities and by societies. It may be seen from the description that the exhibition contains abunda interesting material. It has been visited by thous mothers and it may therefore be hoped that it will con to the welfare of the future generation.

Poisoning by Saccharin.

Dr. Luth of Bajohren, a town on the Russian fr writing to the *Berliner Klinische Wochenschrift*, de the case of a woman who after a dispute with her hu had swallowed about two grammes of saccharin. a medical man arrived about 15 minutes later he fou lying on the floor and her condition was at first supp be due to alcoholic intoxication. She was unconscio face was flushed, she foamed at the mouth, and su from convulsive attacks with choking; her respiratio frequent and her pulse was weak, very quick, mittent, and irregular. Under artificial respiratio massage of the heart the pulse within half an became stronger and regular and the respiration b normal. After about 45 minutes the patient awoke an quite well. Poisoning by saccharin is rather rare. remarkable that severe symptoms occurred within only minutes and as rapidly disappeared. In Germany sacc is sold to the public only on medical prescription an woman had therefore purchased the drug from a neighbo Russian pharmacy.

The Association for the Prevention of Venereal Diseas

The German Association for the Prevention of Ven

Accurate Labels on Patent Medicines.

Public interest has been aroused to the dangers of patent medicines by investigations which have revealed the fact that many of them contain such dangerous ingredients as acetanilid, cocaine, morphine, and wood alcohol. Occasional deaths have been attributed to the free use of these medicines by the public. To regulate the sale of these drugs a Bill has been introduced into the New York legislature by a society of physicians which prohibits the manufacture and sale of medicinal preparations, including so-called "foods," which contain alcohol or certain other narcotic or potent drugs, unless the presence and percentage of such ingredients are revealed on the label in plain English. Where alcohol has been used as a solvent, preservative, or for any other purpose it is deemed an ingredient in the medicine. The label shall constitute a warranty which may be availed of by an injured party. The Bill does not apply to preparations intended solely for external use, or to the dispensing of compounds or prescriptions by legally authorised physicians, dentists, or veterinarians, or to preparations in the pharmacopœia of the United States or the National Formulary unless sold under a proprietary name or trade mark.

Euthanasia.

The question of legalising the act of taking the life of a patient by a physician under certain conditions, has taken an acute form by the introduction of a Bill in the Iowa State legislature making the necessary provision for such a procedure. The Bill is aimed to secure an immediately painless death to persons suffering from a painful disease which will certainly end in death, and to prevent the rearing of hideously deformed children and hopelessly idiotic children. The Bill requires that at least three physicians and the county coroner must unanimously agree to, and participate in, the act, and the consent of the nearest relative and, if possible, that of the patient must be obtained. Any deviation from the proceedings described constitutes murder and subjects the offender to the penalty of murder. The Bill provides a heavy fine for any physician who fails to perform his duty under this measure and also prescribes the usual penalty for murder in the first degree in cases of abuse of the law.

Japanese Naval Sanitation.

At a dinner given at Chicago to Baron Takaki, surgeon-general of the Japanese navy, the distinguished guest stated that when he entered the navy three-fourths of the entire sick list were made up of patients suffering from beri-beri. In his study of the conditions under which the disease appeared he concluded that the ration of the navy contained too great a proportion of carbohydrates and too little albuminates, for he discovered that the prevalence of beri-beri varied directly with the variation of these food constituents. He endeavoured to change the constituents of the ration by the issue of barley in place of part of the rice ration. Strenuous opposition was made to the change by the officers and men and it required a long and severe struggle to effect the reform, but he finally succeeded and beri-beri practically ceased to exist in the navy. He stated that this disease can be artificially produced and that it can be prevented by diet. Referring to the dead and wounded in the Russo-Japanese war he said that up to Dec. 5th, 1905, the total number of dead and wounded was 3639, of whom 1892 died instantly and 117 died subsequently, leaving a balance of 1630. The death-rate was 54 per cent., and more than 90 per cent. of the wounded returned to duty.

Health Conditions on the Isthmus.

The constant agitation in regard to the health conditions on the Isthmus maintains an active public interest in the affairs of the Panama Canal enterprise. The unfavourable reports of transient visitors to the region of the canal operations have lately caused much anxiety on the part of Congress and have led to very critical inquiry by its committee as to the actual sanitary conditions existing there. The report of the chief sanitary officer, Surgeon Gorgas, shows conclusively that the health of the labourers on the canal is remarkably good cons[illegible] the fact that these labourers are largely unac[illegible] January there was an average of 22,000 empl[illegible] daily number sick was 503, [illegible]

March 24th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Pasteur Institute.

The usefulness of the Pasteur Institute at Kasauli is becoming more recognised and with each succeeding year a larger number of patients resort to it for treatment. Last year there were [illegible] patients as against [illegible] for 1904. Of last year's patients [illegible] were Europeans and [illegible] were Indians. Although provinces near the institute naturally contribute the largest numbers, all parts of India send patients. Burma, Assam, Madras, Sikkim, and even Ceylon and Aden each sent a few. The present director is Captain G. Lamb, I.M.S., who was appointed last year when Lieutenant-Colonel D. Semple, R.A.M.C., the former director, was appointed the head of the Central Research Institute. Of the cases treated [illegible] were for *dog-bites* and [illegible] were for *jackal-bites*. Three cases developed hydrophobia while under treatment: two of these were the result of bites from jackals. It should not be forgotten that besides the work in treating cases of rabies the Institute prepares antitoxic sera for diphtheria, tetanus, and snake venom. The total value of these sera issued amounted to Rs. [illegible]. The anti-venomous serum now issued is prepared with a mixture of cobra and other poison.

The Proposed X Ray Institute at Dehra Dun.

It is announced that the Government of India has decided, with the approval of the Secretary of State, to establish an institute in India as a centre for the practical instruction of medical officers and subordinates in the use and management of the x ray apparatus and as a depôt for the storage and repair of such apparatus. The Institute will be located at Dehra Dun and will be under the charge of an officer of the Indian Medical Service. Classes of instruction will extend over a period of three months and facilities will be given to officers who may be desirous of acquiring this special knowledge.

Rat Fleas and Plague: Further Experiments.

Experiments have recently been continued in Bombay for the purpose of proving that rat fleas carry plague not only from rat to rat but from rat to man. Amongst other experiments, a room was selected in which a rat that had died from plague had been found. In this room animals were placed, some being protected by fine metallic gauze, &c., around their cages in order to keep away the fleas, and others were left without these precautions. The unprotected animals sickened and died and rat fleas infected with plague were found on them. The protected animals escaped. In another experiment houses were selected in which cases of plague had occurred and in which rats dead from plague had also been found. The people were removed and then in each house captive animals were placed, some being protected as before described and others not. The result was that those animals which were protected from fleas remained sound while the others were attacked with plague and died. The health department in Bombay is taking energetic measures with regard to the rats found in the streets and houses. Where plague rats are found the houses are marked and disinfected and the occupants are warned. Rat poison is also being largely used. In Calcutta, also, an active crusade is being undertaken against the rats. Rewards for live rats seem to have proved successful and large numbers are destroyed daily.

Miscellanea.

The Royal shoot at Nepaul, for which such great preparations had been made, was broken off on account of the occurrence of cholera in the Maharajah's camp. The disease spread amongst the mahouts and the special man for the Prince's elephant was the first to succumb.—The health returns for the British army in India for 1905 promise to show a still further improvement. Preliminary reports have so far only been issued but these show that malaria and "contagious diseases" have declined and that the mortality from enteric fever has been much less.—Plague of a virulent type is reported to have broken out in Seistan and it is presumed that the disease reached Seistan through the Persian Gulf. *Plague now prevails on each side of Baluchistan.* There is no doubt that this new centre of infection increases the danger of plague working its way into Europe.—It is not generally known *that very considerable numbers* of the population in the United Provinces, the Punjab, Rajputana,

LIONEL SMITH BEALE, M.B. LOND., F.R.C.P. LOND., F.R.S.,
EMERITUS PROFESSOR OF MEDICINE IN KING'S COLLEGE, LONDON, CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL.

Obituary.

LIONEL SMITH BEALE, M.B. LOND., F.R.C.P. LOND., F.R.S.,

EMERITUS PROFESSOR OF MEDICINE IN KING'S COLLEGE, LONDON; CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL.

Lionel Smith Beale was born on Feb. 5th, 1828, in a house close to the church of St. Paul, Covent Garden. He was the only son of Lionel John Beale, M.R.C.S., who practised at 108, Long Acre, and was known in connexion with public health matters as they were understood at that day. His early education was conducted at a private school at Highgate and later at King's College School, whence he entered the medical department of King's College, London. The manner in which he worked as a student is well brought out by the following facts. As early as 1841 he signed an indenture as an apprentice to Joseph Rose, surgeon and apothecary, of Islington. In 1847 he matriculated at the University of London with honours in chemistry and zoology, and in the same year went to Oxford as anatomical assistant in the museum to the late Sir Henry Acland, then the curator. He held this post for two years, being succeeded by Victor Carus of Leipsic. Upon leaving Oxford he began his professional examinations. He passed the first M.B. London in 1849, and in the same year obtained the licence of the Society of Apothecaries and also a certificate stating that he had conducted at the request of the Government Board of Health (the Medical Department of the Privy Council whose work was later transferred to the Local Government Board) a house-to-house visitation at Windsor during the cholera epidemic. This was a most laborious commission and when we remember Beale's youthfulness the amount of work which he found time to get through and the amount of responsibility laid upon him and accepted by him appear marvellous. In 1850–51 he was elected resident physician to King's College Hospital and in the latter year he obtained the degree of M.B. Lond. at the age of 23. It is a singular circumstance that he never proceeded to the doctorate, though the most pronounced purist would hesitate to withhold from him the title of "Dr."

The particular direction of his interests soon showed itself. In 1852 he established a private laboratory where he taught the use of the microscope and gave courses of instruction in physiological chemistry and minute anatomy, normal and morbid. He became at once recognised as a learned and lucid teacher and in 1853 he was appointed professor of physiology in King's College, while it is an interesting fact that no less a person than Professor Huxley, later to be his opponent in many well-fought-out arguments, was one of the candidates for the post. During these early years of his professional life he received much help and good advice from his seniors, notably from Dr. R. B. Todd, Mr. Sambrooke, and Mr. Robert Cheese, three names familiar to all who have worked in King's College Hospital. He was seen from the first to be developing into a scientific physician, but the rapidity of his advance seems incredible to those who realise what medical education means at the present day. He was, of course, a tireless worker, for during the time of his first professorship he was incessantly writing papers for the Royal Society, doing original microscopical work, and teaching and lecturing in many places. Between the years 1851 and 1858 he published over 100 papers, most of them fully illustrated by his own hand, and although these papers are of varying interest and value they laid the foundation of his fame as a man of science and connected his name for the future in men's minds with the famous band of workers at King's College at that date. The names of Todd, J. E. Bowman, and Beale are revered as successive professors of physiology who had as their colleagues Richard Partridge in anatomy, J. F. Daniell and W. A. Miller in chemistry, George Johnson in materia medica, William Fergusson in surgery, Thomas Watson and George Budd in medicine, and Arthur Farre in midwifery. Having been appointed to the chair of physiology at the early age of 25 years it is not surprising to find that not one of his first colleagues survives him, and in considering the chief interest of his life of work it is equally sad to realise that death has already removed those with whom he long maintained many vigorous controversies. When he was only 29 years of age he published the first edition of his book, "How to Work with the Microscope," and the opening words of the preface indicate thus early some characteristics for which subsequent generations of students and observers have been grateful. The book was undertaken, he says, from "an earnest desire to assist in diffusing a love for microscopical inquiry, not less for the pleasure it affords to the student than from a conviction of its real utility and increasing practical value in promoting advancement"; and every page of his book carried out the double promise. It will probably be of interest to note that in the third edition published in 1865 the author not only depicted bacteria and the large bipolar nerve cells from the lumbar nerves of the green tree-frog, but he also included drawings of amœboid movements, concerning which he stated "the nature of these movements has not yet been explained, but I consider them to be 'vital' movements." Such things show well how arduous and exact Beale's researches were, and well illustrate the following brief note which we have received from Professor W. Osler. "The influence of Dr. Beale," writes Professor Osler, "as a scientific investigator and as a clinical physician was much more widespread than perhaps was recognised in London or Great Britain at large. In part at least the unfortunate terminology employed was responsible for the unpopularity of his views in some quarters. His early histological studies were of great value, while as practical physicians we must always be thankful to him for the stimulating work which he did in medical microscopy. His two well known books, 'How to Work with the Microscope' and 'The Microscope in Medicine,' were of the greatest service to two generations of medical students. Many practical points which he introduced in technique, while now superseded, formed important steps in the progress of the art. Both in Canada and the United States there are scores of men of my day who, like myself, knew Dr. Beale only through his writings, who will hear of the death of their old teacher with sincere regret and who will recall with gratitude labours which so often helped to lighten their own."

In 1860 he became professor of pathology in King's College, having previously for several years delivered systematic lectures on morbid anatomy, and during that time he devoted a large amount of time to a consideration of the Darwinian theory and its influence on current philosophical thought. This subject in some form was continually revived in his lectures both while he was professor of pathology and later when he became professor of medicine in the College, and he never wearied in denouncing all who sought to explain the mysteries of life as the outcome of physico-chemical laws. In his book on "Protoplasm or Life, Matter and Mind," he endeavoured to draw attention to the facts and arguments by which the theory of vital action is supported as against purely physical doctrines of life. In this book prominence was given to the many objections to the universal application of physical causation, the mechanical doctrines of life, and the assumed potency of matter to form all living things and to give origin to all vital action. Undoubtedly his eloquent and forcible siding with what may be termed spiritual views gained enormously in force by his familiarity with the microscope and with exact scientific methods. His training and habits were so exactly those that should have made a materialist of him that his deep religious feeling came as an arresting surprise; at the same time his published work was founded on such accurate research that his views could not be regarded as those of a mere mystic.

In 1876 he became professor of medicine and his practical skill as a therapeutist was displayed in his lectures, some of which were published in a well-known volume, "On Slight Ailments: their Nature and Treatment." The title of this book sufficiently indicates its general scope, but throughout its pages will be found not only valuable hints and "wrinkles" which the author had learnt from his old masters but also continual encouragement to assume a cheery optimism, an attitude which was characteristic of the lecturer himself. During this period of Beale's life he became a well-known and highly valued consultant physician, and many generations of students at King's College Hospital, as well as many patients both in the hospital and in private life, testified to the shrewdness of his knowledge and the kindness of his heart. In 1896 he retired from the professorship of medicine, having thus had no less than 43 years of professorial life, during 40 of which he had been physician to

LIONEL SMITH BEALE, M.B. LOND., F.R.C.P. LOND., F.R.S.,
EMERITUS PROFESSOR OF MEDICINE IN KING'S COLLEGE, LONDON, CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL.

Army Medical Reserve. He went to Blackburn over 30 years ago as assistant to the late Dr. Irving, whom he subsequently joined as a partner, and on Dr. Irving's death carried on the practice which under his care became one of the largest in the district. Dr. Martin fulfilled in himself the traditions of his inheritance, and during the later years of his life never appeared happier than when stimulating his younger colleagues with that zeal and enthusiasm for their work with which he was imbued. Those who were intimately acquainted with him recognised for some time symptoms of failing health, but though he was known to be suffering from an attack of erysipelas his death from cerebral hæmorrhage came as a shock to all. The greatest sympathy is extended to his widow and family, both by his numerous friends and also by his professional brethren who recognise that by his death they have lost not merely a worthy colleague but a competent and trustworthy leader.

THOMAS EVANS, M.D. EDIN., L.R.C.S. EDIN.

Dr. Thomas Evans died recently at his residence, Park House, Newquay, Cardiganshire, in his sixty-fourth year. He was born at Newquay and received his medical education at the University of Edinburgh, where he graduated as MD. in 1865, subsequently obtaining the diploma of L.R.C.S. Edin. in 1870. After holding the appointment of senior house surgeon at the Royal Portsmouth Hospital, Dr. Evans commenced practice at Newquay, where he filled several public appointments, being medical officer of health of the Aberayron rural district and also of the Newquay urban district. He was medical officer and public vaccinator of the Llandisilio district of the Aberayron union and Admiralty surgeon and agent. Dr. Evans was highly respected at Newquay; he was chairman of the old school board and a manager of the Newquay group of schools. He leaves a widow and five children, with whom much sympathy is felt. The funeral, which took place on March 30th, was largely attended.

JESSIE MACLAREN MACGREGOR, M.D. EDIN., L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

NEWS has just been received in Edinburgh of the death of Dr. Jessie MacLaren MacGregor in Denver, U.S.A., after a short illness. Dr. MacGregor was well known in Edinburgh, where she received her medical education and where she practised until about a year ago when she went to Denver, attracted there by family ties. She took the Scottish triple qualification in 1892. As soon as the University opened its degrees to women she at once set herself to prepare for the examinations and graduated as M.B., C.M. in 1896. Three years later, in 1899, she took the M.D. degree and was the first lady graduate of Edinburgh to be awarded a gold medal for her thesis. For a short time she held the post of registrar to the Royal Hospital for Sick Children and at the time when she left Edinburgh she was a member of the staff of the Hospital for Women and Children. She published a book on "The Pathology of the Endometrium" which has been well received and which contains the record of extensive observations. She was an able and popular practitioner and was taking quite a foremost place amongst those of her sex in Edinburgh, so that her prospects were bright and her friends there naturally regretted her determination to cross the Atlantic. In Denver she soon obtained work in the University and there was every prospect that she would before long have got her share of clinical work. Her unlooked-for death has cast a gloom that is all the deeper in view of the regret which was aroused by her decision to abandon her position in Edinburgh.

GLOUCESTERSHIRE INFIRMARY AND EYE INSTITUTION.—The annual meeting of the subscribers to this institution was held on March 29th. The medical report was satisfactory but the financial statement showed that an unfavourable balance of £596 remained. The chairman (Colonel Hayward) referred to the fact that during the year £188 were spent in spectacles and appealed to the committee for strict inquiry into the circumstances of patients who obtained these articles from the infirmary. £11,144 had been spent on building and improvements; of this sum £7800 had received, leaving £3310 still to be raised.

Medical News.

UNIVERSITY OF LIVERPOOL: DIPLOMA IN TROPICAL MEDICINE.—The examinations for the Diploma in Tropical Medicine were held on March 26th, 27th, and 28th. The following candidates satisfied the examiners and have been recommended for the diploma:—

F. A. Arnold, M.B., D.P.H.; J. B. Bate, L.S.A.; J. Dundas, M.B.; Major N. Faichnie, M.B., R.A.M.C.; D. F. Mackenzie, M.B.; Major A. Pearse, D.P.H., R.A.M.C.; and Captain R. D. Willcocks, M.B., I.M.S.

TRINITY COLLEGE, DUBLIN.—At examinations held in Hilary term the following candidates were successful:—

FINAL EXAMINATION IN MEDICINE.

Part I.—Thomas O. Graham, Francis W. H. Bigley, Cecil T. Conyngham, Henry D. Woodroffe, Ernest C. Crawford, Charles G. Sherlock, Arthur E. Knapp, Albert T. J. M'Creery, Francis O'B. Kennedy, Wilfred L. Hogan, Henry B. Leech, John A. Hartley, Joseph C. Ridgway, Wallace D. Mitchell, and George H. Stack.

Part II., Medicine.—Samuel G. S. Haughton, Gustav W. Thompson, John D. Sands, Robert A. Askins, John C. P. Beatty, Basil G. Brooke, Thomas H. Peyton, Francis Casement, Francis Coppinger, George Dougan, George G. Vickery, Ralph S. Oldham, and Edward Gibbon.

Part II., Surgery.—John D. Sands, Basil G. Brooke, Robert R. Jackson, Ralph S. Oldham, Samuel G. S. Haughton, Alfred G. Alexander, Hercules J. Knox, and Gustav W. Thompson.

INTERMEDIATE MEDICAL EXAMINATION.

Part II.—William Pearson, Johannes C. Pretorius, Robert E. Wright, William E. Hopkins, John A. W. Ponton, William S. Thacker, David J. Miller, Dixie P. Clement, James F. Clarke, Wilfred J. Dunn, Thomas P. Dowley, Alfred H. Smith, James C. C. Hogan, Gordon A. Jackson, John H. Morton, Thomas P. S. Eves, Norman P. Jewell, Allman T. Powell, Julian B. Jones, James R. Yourell, Ernest C. Lambkin, Oliver Gogarty, Edmund H. Sheehan, Alexander S. M. Winder, William Knapp, and Frank R. Seymour.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. Arriëns Kappers has been recognised as *privat-docent* of Histology.—*Berlin:* Dr. Adolf Passow has been appointed Director of the University Aural Clinic in succession to Dr. August Lucae who, having reached the age of 70 years, is retiring.—*Breslau:* Dr. Triepel of Greifswald has been appointed Honorary Extraordinary Professor of Anatomy.—*Copenhagen:* Miss Eli Müller, M.D., has been recognised as *privat docent* of Midwifery.—*Freiburg:* Dr. Ludwig Aschoff has been appointed to succeed the late Dr. Ziegler as Professor of Pathological Anatomy.—*Göttingen:* Dr. Wendeburg and Dr. Heiderich have been recognised as *privat-docenten* of Neurology and Anatomy.—*Halle:* Dr. Alexander Stieda has been recognised as *privat-docent* of Internal Medicine.—*Kiel:* Dr. Reinhold Ruge, *privat-docent* of the History and Geography of Medical Sciences, has been granted the title of Professor. Dr. Victor Klingmüller of Breslau has been appointed Extraordinary Professor of Dermatology in place of Professor von Düring who is going to Dresden.—*Kharkoff:* Dr. Kiyanitsyn of Kieff has been appointed Extraordinary Professor of Hygiene.—*Königsberg:* Dr. Klieneberger has been recognised as *privat-docent* of Internal Medicine and Dr. Joachim as *privat-docent* of Medicine. Dr. Rudolph Kafemann, *privat-docent* of Laryngology, has been promoted to an honorary professorship.—*Leipsic:* Dr. Heinrich Klien has been recognised as *privat-docent* of Neurology.—*Munich:* Dr. Oberndorfer has been recognised as *privat-docent* of Pathological Anatomy.—*Padua:* Dr. Giuseppe Albertotti of Modena has been appointed to the chair of Ophthalmology.—*Pavia:* Dr. Giuseppe Muscatello has been appointed Extraordinary Professor of External Pathology.—*Rome:* Dr. Ercole Tranquilli has been recognised as *privat-docent* of Internal Pathology.—*Rostock:* Dr. Joseph Meinertz has been recognised as *privat-docent* of Internal Medicine.—*Strasburg:* Dr. Albrecht Bethe, assistant in the Physiological Institute, Dr. Edwin Faust, assistant in the Pharmacological Institute, Dr. Julius Klein, *privat-docent* of Gynæcology, and Dr. Karl Spiro, assistant in the Institute of Physiological Chemistry, have been promoted to Professorships.

SHEFFIELD AND DISTRICT EDINBURGH UNIVERSITY CLUB.—The first annual dinner of the above club took place on March 24th at the Royal Victoria Station Hotel, Sheffield. The club has started with a membership of 57 and a company of 90 was present, with Dr. J. H. Keeling, the *doyen* of the medical profession in Sheffield, in the chair. Professor T. Annandale was the guest of the evening and amongst other guests present were Professor W. M. Hicks,

alcohol accelerated the spread of tuberculosis; it also weakened the body's defences against all *diseases* and in most cases increased the latter.

THE BRITISH MEDICAL BENEVOLENT FUND.—A bank-note for £10 from "Anon." has been received by the honorary treasurer of the British Medical Benevolent Fund.

BRISTOL ROYAL INFIRMARY.—The sum of £45,013 has been received towards the "£50,000 Fund" required for bringing the Bristol Royal Infirmary thoroughly up to modern requirements.

DONATIONS AND BEQUESTS.—A donation of £1000 has been received by the treasurer of the Leeds General Infirmary from Mrs. Cooke of Leeds to endow a bed in memory of her husband, the late Mr. A. Cooke.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—The thirty-first annual meeting of the supporters of this hospital was recently held in the town hall, Manchester, under the presidency of the Lord Mayor (Mr. J. H. Thewlis). The report tells of increased and increasing work. The 50 beds at the Bowdon in-patient department had been fully occupied. At the out-patient department at Hardman-street, where not only consumptive patients are treated but also those suffering from other diseases of the respiratory organs, throat, nose, and upper air passages, 11,210 cases were attended to, while the Crossley Sanatorium at Delamere has begun very auspiciously its beneficent work. Mr. Crossley not only built the sanatorium but supplied the complete furnishing and equipment, including the plant for electric lighting, heating, steam laundry, water-supply, and scheme for the disposal of sewage, and it is safe to say that it stands high in the list of institutions for the treatment of consumption. The grounds are 66 acres in extent and, with the exception of meal times, the patients are out the whole of the day, either lying on their couches in the shelters or taking exercise as prescribed by the medical officers. Of course there is the usual appeal for funds but Mr. Crossley, who was present, thought that they were fortunate in having only a deficiency of £1800 on the two accounts in the first year of so large an undertaking. He wished medical men would take more interest in the hospital and send more paying patients. "This idea had been obtained from Germany." The lowest rate of payment for these patients was two guineas a week, while the ordinary cases paid on an average 3*s.* a week. About a dozen of the patients were present, all looking hale and well. They will have to continue to live as nearly as possible in the conditions that led to their improved health, which is, of course, the hardest problem of all.

CENTRAL MIDWIVES BOARD.—The members of the Central Midwives Board held a meeting on March 29th at 6, Suffolk-street, London, Dr. F. H. Champneys being in the chair.—A letter was read from Dr. E Walford (medical officer of health of Cardiff) forwarding a copy of a resolution passed by the local supervising authority at Cardiff asking the Board to make Cardiff one of the provincial centres for the Board's examinations. Some of the candidates did not understand the English language and it was urged that this difficulty would be obviated by having a provincial centre at Cardiff. After a discussion the matter was referred to the standing committee. The report of the meeting of examiners held on March 20th to consider the question of an official handbook for midwives was received. The report states that it was moved and seconded "that the examiners recommend to the Board the publication of an official handbook for midwives." It was decided that the consideration of this recommendation should be postponed for six months. The clerk of the London County Council having reported that two midwives were guilty of persistent disobedience to Rule E, 19 (b), and had announced their intention of not complying with the rule, the board directed that the midwives in question should be called on to furnish an explanation of the fact alleged against them by the London County Council. At a meeting of the Board on Jan. 30th the name of Mary Ann George was removed from the roll and instructions were given that the papers in the case were to be sent to the Pr cutor for his consideration of the fo concerr g of a certificate of good

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Army Medical Reserve.

IN THE LANCET of March 31st an outline was given of the n
Medical Reserve scheme. The subject was discussed in the
Commons on the Army Estimates when Mr. HALDANE g
additional particulars. He said that it was perfectly plain t
their increasing burdens no nation—certainly not this natio
bear the charges of keeping everything in the time of peace
war level. Therefore the War Office has set itself to act upon
ciple of asking itself what steps it could take to prepare in time
things in skeleton so that they might be clothed with flesh a
when war broke out. The outbreak of war was the only test t
be applied. The very efficient director-general of the Army
Service had had the matter under consideration lately and a s
a new scheme had been made. It was recognised that in order
the civilian surgeon—for civilian surgeon he would be for t
during peace time—efficient in time of war he must go through
training. Even the distinguished men who went to Sout
at the time of the war found themselves very much out of it wh
came to do the special work which the army surgeon had to
(Mr. HALDANE) did not himself realise the reason for that clea
he read one of the latest treatises upon military hygiene. The
the vote for the Army Medical Establishment a sum of £4
reserve of civilian surgeons and what the War Office proposed t
to take 450 young medical men who were willing to enter the ne
Medical Reserve and to train them. They would be subject to t
that govern the employment of reserve officers generally an
have the rank of lieutenant on joining with promotion to capta
three and a half years' satisfactory service. A practitioner join
reserve would have to undergo a course of special training at th
of the Royal Army Medical Corps at Aldershot. During th
he would receive the pay and allowances of an officer of h
in the Royal Army Medical Corps. If this probationary pe
service was satisfactory he would be confirmed in his rank and
in his second and third years a retaining fee of £20 a year. He n
course, do something for that money and he would be called u
undergo another period of instruction preparatory to pass
examination which was necessary for promotion to the r
captain. During this second course, the duration of which
be one month, he would be paid as before. After pro
to the rank of captain his retaining fee would be £25 a
It was proposed to limit the period in the reserve to seven
by which time the surgeon would have learned enough wi
civilian knowledge to make him able to take the field wi
requisite qualifications. The reserve would be primarily comp
civilian surgeons, but it was not intended to exclude officers
auxiliary forces and medical officers of the Volunteers, provide
were seconded in their Volunteer corps. These reserve officers
resign their commissions upon the usual conditions. It was also
to get a certain number of reserve attendants in the same way.

Charge against Medical Practitioners.

In the course of the debate on the second reading of the P
tion of Corruption Bill in the House of Commons on Apr
Mr. VIVIAN alleged that a practice existed among a certain c
medical men of accepting commissions for placing orders for coff
the patients whom they were attending. The statement was rec
with cries of dissent, but Mr. VIVIAN reiterated the allegatio
asked the House to picture the situation created when the m
attendant knew that if the patient died the insurance money
be there to pay for the coffin and the commission, while if the pa
lived there would be no money to pay even the medical fees.
tunately, no medical Member was in the House to take up the m
at any rate no reply was attempted.

England G F, M D Cantab, has been appointed Certifying Surgeon under the Factory and Workshop Act for the Winchester District of the county of Hants

Fairbank, H A T, M S Lond, F R C S Eng, has been appointed Orthopædic Surgeon to Charing Cross Hospital

Fletcher, J. R., L R C P Edin, L F P S Glasg has been appointed Certifying Surgeon under the Factory and Workshop Act for the Sherston District of the county of Wilts

Howard-Jones, J, M R C S, L R C P Lond has been appointed Certifying Surgeon under the Factory and Workshop Act for the Worthen District of the county of Salop

Lambert, Frederick Samuel, M R C S, L R C P Lond, has been appointed Medical Officer to the Lincoln Post Office

Lewis, Cyril, M D, C M Edin, *has been appointed Honorary* Assistant Physician to the Cardiff Infirmary

Middlemiss, W J F, L.D S Edin, has been appointed Dental Surgeon to the Troops in Ireland

Milne, Leslie J, M D, C M Aberd, has been appointed Certifying Factory Surgeon for Mirfield, Ravensthorpe, and Thornhill, and Medical Officer of Health of Mirfield and Medical Officer to the Crossley Infectious Hospital.

Paterson, Donald Rose, M D, C M Edin., M R C P Lond, has been appointed Honorary Surgeon to the Ear, Throat, and Nose Department at the Cardiff Infirmary

Pearce, Arthur, M R C S L.S A, has been re-appointed Medical Officer of Health of the Salcombe (Devon) Urban District.

Ridout, C A **Scott**, M S, M B *Lond*, F R C S *Eng*, has been appointed Honorary Pathologist to the Royal Portsmouth Hospital

Rudge, Frederick Henry, L R C P Lond, M R C S, has been appointed Resident Obstetric Officer at the Bristol Royal Infirmary

Sheppard, Arthur Lewin, M B, B S Durh., has been appointed House Physician at the Bristol Royal Infirmary

Short, Arthur Rendle, M D, B S, B Sc. Lond, has been appointed Senior Resident Medical Officer at the Bristol Royal Infirmary

Smith, L. Shingleton, L.R.C P *Lond*, M R.C S, has been appointed Junior House Surgeon at the Bristol Royal Infirmary

Wright, A. J, L R.C P Lond, M R C S, has been appointed Casualty Officer at the Bristol Royal Infirmary

Wyand, E H, L D S Eng, has been appointed Dental Surgeon to the Troops at Aldershot.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

Aberdeen (New) Poorhouse.—Resident Assistant Medical Officer Salary £80 *per annum, with board, attendance, &c.*

Ayr County Hospital.—Resident House Surgeon Salary £70 per annum, with board and residence.

Bridgwater Hospital.—House Surgeon Salary £80 a year, with board and residence

Buxton, Derbyshire, Devonshire Hospital.—Assistant House Surgeon Salary £70 per annum, with apartments, board, and laundry

Canterbury, Kent and Canterbury Hospital.—House Physician, unmarried Salary £90 a year, with board and lodging

Carlisle Non Provident Dispensary—Resident Medical Officer Salary £150 per annum, with apartments

Carnegie Dunfermline Trustees—Assistant Medical Officer (female) Salary £200 per annum

Central London Throat and Ear Hospital, *Gray's Inn road, W C* —Honorary Registrar

Chester General Infirmary—House Physician Salary £90 per annum, with residence and maintenance.

Committee for the Study of Special Diseases—Research Scholarship of £100 per annum for six months

Cotford, Taunton, Somerset and Bath Asylum—Assistant Medical Officer, unmarried Salary £140 per annum, increasing to £160, with apartments, board, &c

Dudley, Guest Hospital.—Assistant House Surgeon for six months Salary £40 per annum, with residence, board, and washing

East London Hospital for Children and Dispensary for Women, Shadwell, E —Assistant Surgeon

Edmonton Urban District Council.—Medical Officer of Health Salary £350, payable monthly

Garlands, Carlisle, Cumberland and Westmorland Asylum—Junior Assistant Medical Officer Salary £130 per annum, with board and lodging

Gartloch Asylum, Gartcosh.—Assistant Medical Officer Salary £125, with board and lodging

Hospital for Women, Soho square, W —House Physician for six months Salary £30

Hull Royal Infirmary—Honorary Assistant Ophthalmic Surgeon

Ingham Infirmary and South Shields and Westoe Dispensary —*Senior House Surgeon. Salary* £100 per annum, with residence, board, and washing

Knighton Union—District Medical Officer Salary £40 per annum

Leith Hospital.—Medical Registrar

Liverpool Infirmary for Children—House Surgeon Salary £100 per annum, with board and lodging

Liverpool, Royal Southern Hospital.—Junior House Surgeon Salary 60 guineas per annum

Liverpool Stanley Hospital.—House Surgeon Salary £60 per annum, with board, residence, and washing

London Lock Hospital.—House Surgeon to the Female Hospital. Salary £80 per annum, with board, lodging, and washing

Macclesfield General Infirmary—Senior House Surgeon Salary £100 for the first year, with an increase of £10 the second, with board and residence

Maidstone, West Kent General Hospital.—House Surgeon Salary £100, with board and residence Also Assistant House Surgeon and Anæsthetist Salary £60 with board and residence

Manchester Hospital for Consumption and Diseases of Throat and Chest—Resident Medical Officer for the In- Department at Bowdon Cheshire Salary £100 per annum, board apartments washing, and railway contract.

Manchester Monsall Fever Hospital.—Fourth Medical As Salary £100 per annum, *with board, lodging*, and washing

Margate Royal Sea Bathing Hospital.—Resident Su as Junior and Senior for six months each. Salary at *rate* and £120 per annum, with board and residence.

Miller Hospital and Royal Kent Dispensary, Greenwich S E —Honorary Medical Officer for X Ray and Electro- peutical Department.

Paddington Green Children's Hospital, London, W— *Physician*, also House Surgeon, both for six months. Sa rate of 50 guineas a year, with board and residence.

Paisley, Royal Alexandra Infirmary, Barbour Park.— Surgeon Salary £40, with bed and board.

Poplar Hospital for Accidents, Poplar, E.—Assistant Surgeon for six months Salary at rate of £20 per annum, board and residence

Reigate Town Council and Rural District Council.—M Officer of Health Salary £500 *per annum*

Royal College of Surgeons of England—Four Examiner Anatomy and Four Examiners in Physiology

Royal Ear Hospital, Dean street Soho, W —House Surgeon, resident. Honorarium at rate of £40 per annum. Also C Assistants.

Royal Eye Hospital, Southwark, S E.—House Surgeon f *months renewable Salary 50 guineas per annum, with boar* residence Also Clinical Assistants

Royal Free Hospital Gray's Inn road, W C —House Phy Casualty House Surgeon, both for six months Board, vided Also Resident House Physician and Resident Surgeon (Female) Board &c., provided Also Assistan Clinical Pathologist. Salary £50 per annum Also A Anæsthetist. Both females

Royal Halifax Infirmary—Second House Surgeon, un Salary £100 per annum, with residence, board, and washing

Royal Hospital for Diseases of the Chest, City road, Resident Medical Officer for six months Salary at rate per annum, with apartments, board, and washing

Royal Portsmouth Hospital, Portsmouth —House P for six months Salary at rate of £50 per annum, with residence, and laundry

St George's Union Infirmary, Fulham road, S W —Second ant Medical Officer Salary £120 per annum, with bo dence, and washing

Shrewsbury, Salop Infirmary—House Surgeon, unmarried. £100 per annum, with board washing, and residence.

Swansea General and Eye Hospital.—House Surgeon. S rate of £50 per annum first six months, £75 per annum af board, apartments, washing, and attendance.

Tottenham Hospital, *London*, N —House *Surgeon*, *Hou* sician Casualty Officer, all for six months Salaries at £90, £60, and £40 per annum respectively, with board, re and laundry

Virginia Water, Surrey, Holloway Sanatorium, St. Heath —Junior Assistant Medical Officer Salary £175 per *with board, lodging, washing*, &c.

West Riding of Yorkshire—Assistant to County Medical Salary £250 per annum, rising to £400

The Chief Inspector of Factories, Home Office, S W, gives n a vacancy as Certifying Surgeon under the Factory and shop Act at Uppingham, in the county of Rutland.

Births, Marriages, and Deaths.

BIRTHS.

Alcock.—On March 31st, at Norfolk Mansions, Battersea Park, S W, the wife of N H. Alcock, M D, of a daughter

Carruthers—On March 29th, at Central hill, Norwood, the S W *Carruthers*, M D, *of a daughter*

Letchworth—On April 1st at Fairlight, 156, Parkwood road, mouth E., the wife of T W Letchworth, B A., M.B., L.R C P, of a son

MARRIAGE

Kay—Laver—At St. Martin's Church, Scarborough, on Mar by the Rev A F Mitchell, vicar of St. Augustine's, Sheffie the Ven Archdeacon Mackerness, vicar of St. Martin's borough, *Walter Smith Kay, M D, Medical Superintendent* South Yorkshire Asylum, Wadsley, Sheffield, to Elizabeth widow of Arthur H Laver, M D, of Sheffield

DEATHS.

Beale.—On March 28th, Lionel S Beale, M B, F R.S, F R Emeritus Professor of Medicine in King's College London, sulting Physician to King's College Hospital, aged 78 years.

Buchanan—*On March 22nd, at Sowerby, Thirsk, John Ha* Buchanan, M.D, J P, aged 73 years

Hartford—On March 30th, at Christchurch, Henry William Ha L.R.C.P & L.R C S., aged 52 years

Marriott—On March 20th at Swaffham, Norfolk, Robert Buc Marriott, M R C S, L S A., L.M, aged 75 years

N B —A fee of 5s. is charged for the insertion of Notices of Bir Marriages, and Deaths

We hasten to assure our correspondent that plumbago, which is allotropic carbon, cannot possibly produce the same effects as lead itself when introduced into the system The "blood poisoning" from which her friend suffered had nothing to do with the plumbago of which the pencil was made, and the same results would probably have followed a prick with a pin or a splinter of wood if received under the same conditions as the wound from the pencil. As to children and pencils, they are forbidden to suck them, not on account of any deleterious quality in the plumbago itself, but on account of the danger of the pencil transferring infection from one mouth to another when pencils are distributed indiscriminately A little knowledge has made our correspondent unhappy.

INACCURATE QUOTATION.

IN THE LANCET of March 3rd, 1906, upon p. 595, under the heading, "A Practical Experience with Adrenalin as a Cardiac and Vaso-motor Stimulant," we published an interesting article by Dr H. O. Butler, who narrated his experience of adrenalin, stating it to be a product manufactured by Messrs. Parke, Davis, and Co , in a case where a child appeared moribund from measles and pneumonia. On March 15th the article was substantially quoted in the "Therapist," the title having been altered to "Adrenal-chloride as a Cardiac and Vaso-motor Stimulant," while the fact that the substance used was stated to be manufactured by Messrs Parke, Davis, and Co was suppressed and the word "adrenalin" was altered to "adrenal" almost throughout the article. We do not consider that the "Therapist" is to be complimented in the matter. Messrs A and M. Zimmermann, the proprietors of that paper, manufacture a product called "adrenal-chloride" and the article as altered for appearance in the columns of the "Therapist" wears the appearance of a valuable piece of evidence in favour of adrenal-chloride. The attention of Messrs. A. and M. Zimmermann having been called to the matter we received a letter from that firm pointing out that "in accordance with the nomenclature of Armand Gautier the isolated crystallised compound of the suprarenal capsule should therefore be termed 'adrenal'" We think that this information, whatever its scientific or etymological value, rather misses the point, which is that in THE LANCET a medical man has attributed certain favourable results to a definite substance styled by him and by its manufacturers "adrenalin," whereas in the "Therapist" the article has been altered for quotation so that these results appear to have been obtained by another definite substance. The comparative merits of the two substances are not in question, but one happened to be used in the treatment of the patient while the other was not so used

FEES FROM CORONERS

To the Editors of THE LANCET

SIRS,—I was recently called to a case of sudden death by a messenger who stated to me that the local policeman had sent him for me. On arrival at the house I found an old man, whom I had attended some months before for a suppurating axillary gland, dead The body showed no marks of violence and I was informed that the man had been seen to fall as he walked and that the observer had run to him and found him dead. The policeman asked me to give him "a line" to take to the coroner and he showed me a form of questions provided for such cases which he (the policeman) had to fill up with answers Among these questions were some about previous illnesses and medical man's attendance. There was obviously no reason to suspect any foul play and I was anxious to save the friends from the worry of an inquest, as I had another very critical case in the house at the time I therefore wrote down on a sheet of paper that I had seen the dead body, found no marks of violence, and felt sure that death had resulted from natural causes, signing my name at the foot. The next day the policeman called on me and informed me that there was to be no inquest and handed me 5s from the coroner, asking me to sign a form of receipt "for information given." I hesitated to accept the cash till told by the policeman that recently a neighbouring medical man in a similar case had been so paid by the coroner. It was an entirely new experience to me and I shall be glad to know if the coroner has acted rightly. I had always thought that the coroner could only pay 21s. for evidence given at an inquest At any rate, the 5s was quite inadequate as a fee in this case, seeing that I had to go two miles without any breakfast at 8 A.M. and wasted about an hour and a half. As the coroner apparently accepts some liability, seeing that he has offered a fee, have I any claim on him for an adequate fee?

I am, Sirs, yours faithfully,

COUNTRY DOCTOR.

April 1st, 1906.

*** Our correspondent, in our opinion, acted quite rightly in giving the information asked for and in accepting the proffered fee, and he appears to have no ground for complaint against the coroner. As we understand the facts, there is no question of liability on the part of relatives and he was summoned by a policeman to see a man who had allen in the highway and was believed to be dead. Whether the police would admit liability to the medical man we do not pretend to say, but clearly they do right in seeking medical advice at once rather than in deciding for themselves whether a person found in the condition described is actually dead; and it is equally plain that a medical man should not be expected to give such an attendance gratis. This, however, has nothing to do with the coroner, who in this instance seems to have adopted a businesslike method of obtaining information from the person best qualified to give it in order to guide him as to whether an inquest should be held or not. Further, he has followed the opinion given and has paid for it. The sum of 5s, regarded payment "for information given" in the manner described, is fee upon a larger scale than 21s. earned by attending as a witnes an inquest when the time occupied in waiting to give evidence a the other circumstances of so doing are taken into consideration. is desirable that the payment of a fee for information given to t coroner should be provided for whenever the law relating to inque is remodelled. At present the information is usually expected to given gratis and the practice in this instance is none the less to commended because it is not universal.—ED L.

QUACKS' ADVERTISEMENTS.

THE American quack named Macaura, to whom we alluded recent as having selected the city of Newcastle-on Tyne for his bas operation, continues to advertise profusely in the local papers t story of his exploits. A correspondent sends us a copy of the *Ne castle Evening Chronicle*, dated Saturday, March 31st, 1906, whi contains a column of obviously mendacious rubbish about Macaur inventions, and asks us "Is or is not this a most blameworth action on the part of a paper claiming a high reputation for scr pulous journalism?" It certainly seems to us very regrettable th the *Newcastle Evening Chronicle* should take Macaura's mon and publish his statements, even though the *Newcastle Eveni Chronicle* in so doing only imitates other and no less reputab journals The licence enjoyed by quacks in the existing co ditions of the law is deplorable and we trust that the near futu may see an organised attempt on the part of the medical professi to procure amended legislation in the matter. So long as quacks ca vaunt their medical pretensions in the most unscrupulous way wit out fear of penalty, if only they do not pretend to be register practitioners, so long will the public be practically helpless agai their machinations, and it goes without saying that the profu advertisement, paid or unpaid, given by newspapers to the exploi of charlatans enormously increases the mischief

"CANCER CURES"

IN our issue of Oct. 7th, 1905, p 1046, we commented upon a qu remedy for cancer called the "Aesiab Cancer Cure," of which we g an analysis The active ingredient of the cure was tartar emetic. W now learn from the *Cape Times* of March 8th that the proprietor the nostrum, Mrs Anna Elizabeth van Niekerk, was prosecute under Section 35 of Act 34 of 1891, viz., the Medical and Pharma Act, for having practised as a medical practitioner. The jury fou Mrs. van Niekerk guilty and she was sentenced to pay a fine of £ or to undergo two months' imprisonment.

A NEW SUTURE FOR THE ABDOMINAL WALL.

IN the present issue of THE LANCET, upon p 957, we print a note upon a new form of suture for use in the abdominal wall which ha been introduced by Mr. J. B Pike of Loughborough. It is a attempt to combine the advantages of suturing in layers with th benefits of the single stitch penetrating all the layers of the ab dominal wall The essential point in the stitch is that it passes fro one side of the incision to the other as it traverses the differen layers Since it comes to the surface it can be removed completel and so no buried suture remains Many surgeons appear to mee with much trouble from buried sutures, but other surgeons never, o very rarely, have any trouble with them. It is not improbable th excessive tightness in deep sutures may be the chief cause for thei giving rise to trouble, always supposing that no sepsis is present. Mr. Pike's suture is ingenious, though we think the method has bee already described. We can well imagine that it might prove usef in some circumstances.

COMMUNICATIONS not noticed in our present issue will receive attentio in our next.

METEOROLOGICAL READINGS.

A. *and* M. *Zimmermann*, the proprietors of that paper, manufacture a product called "adrenal-chloride" and the article as altered for appearance in the columns of the "Therapist" wears the appearance of a valuable piece of evidence in favour of adrenal-chloride. The attention of Messrs. A. and M. Zimmermann having been called to the matter we received a letter from that firm pointing out that "in accordance with the nomenclature of Armand Gautier ...... the isolated crystallised compound of the suprarenal capsule should therefore be termed 'adrenal.'" We think that this information, whatever its scientific or etymological value, rather misses the point, which is that in THE LANCET *a medical man has attributed certain favourable* results to a definite substance styled by him and by its manufacturers "adrenalin," whereas in the "Therapist" the article has been altered for quotation so that these results appear to have been obtained by another definite substance. The comparative merits of the two substances are not in question, but one happened to be used in the treatment of the patient while the other was not so used.

FEES FROM CORONERS.

To the Editors of THE LANCET.

SIRS,—I was recently called to a case of sudden death by a messenger who stated to me that the local policeman had sent him for me. On arrival at the house I found an old man, whom I had attended some *months* before for a suppurating axillary gland, dead. The body showed no marks of violence and I was informed that the man had been seen to fall as he walked and that the observer had run to him and found him dead. The *policeman asked me to give him "a line" to take to* the coroner and he showed me a form of questions provided for such cases which he (the policeman) had to fill up with answers. Among these questions were some about previous illnesses and medical man's attendance. There was obviously no reason to suspect any foul play and I was anxious to save the friends from the worry of an inquest, as I had another very critical case in the house at the time. I therefore wrote down on a sheet of paper that I had seen the dead body, found no marks of violence, and felt sure that death had resulted from natural causes, signing my name at the foot. The next day the policeman called on me and informed me that there was to be no inquest and handed *me 5s. from* the coroner, asking me to sign a form of receipt "for information given." I hesitated to accept the cash till told by the policeman that recently a neighbouring medical man in a similar case had been so paid by the coroner. It was an entirely new experience to me and I shall be glad to know if the coroner has acted rightly. I had always thought that the coroner could only pay 21s. for evidence given *at an inquest*. At any rate, the 5s. was quite inadequate as a fee in this case, seeing that I had to go two miles without any breakfast at 8 A.M. and wasted about an hour and a half. As the coroner apparently accepts some *liability, seeing that he* has offered a fee, have I any claim on him for an adequate fee?

I am, Sirs, yours faithfully,
COUNTRY DOCTOR.

April 1st, 1906.

*** Our correspondent, in our opinion, acted quite rightly in giving the information asked for and in accepting the proffered fee, and he appears to have no ground for complaint against the coroner. As we understand the facts, there is no question of liability on the part of relatives and he was summoned *by a policeman* to see a man who had fallen in the highway and was believed to be dead. Whether the police would admit liability to the medical man we do not pretend to say, but clearly they do right in seeking medical advice at once rather than in deciding for themselves whether a person found in the condition described is actually dead; and it is equally plain that a medical man should not be expected to give *such an attendance gratis*. This, however, has nothing to do with the coroner, who in this instance seems to have adopted a businesslike method of obtaining information from the person best qualified to give it in order to guide him as to whether an inquest should be held or not. Further, he has followed the opinion given and has paid for it. The sum of 5s., regarded as payment "for information given" in the manner described, is a fee upon a larger scale than 21s. earned by attending as a witness at an inquest when the time occupied in waiting to give evidence and the other circumstances of so doing are taken into *consideration*. It is desirable that the payment of a fee for information given to the coroner should be provided for whenever the law relating to inquests *is remodelled*. At present the information is usually expected to be given gratis and the practice in this instance is none the less to be commended because it is not universal.—ED. L.

QUACKS' ADVERTISEMENTS.

THE American quack named Macaura, to whom we alluded recently as having selected the city of Newcastle-on-Tyne for his base of operation, continues to advertise profusely in the local papers the story of his exploits. A correspondent sends us a copy of the *Newcastle Evening Chronicle*, dated Saturday, March 31st, 1906, which contains a column of obviously mendacious rubbish about Macaura's inventions, and asks us: "Is or is not this a most blameworthy action on the part of a paper claiming a high reputation for scrupulous journalism?" It certainly seems to us very regrettable that the *Newcastle Evening Chronicle* should take Macaura's money and publish his statements, even though the *Newcastle Evening Chronicle* in so doing only imitates other and no less reputable journals. The licence enjoyed by quacks in the existing conditions of the law is deplorable and we trust that the near future may see an organised attempt on the part of the medical profession to procure amended legislation in the matter. So long as quacks can vaunt their medical pretensions in the most unscrupulous way *without fear of penalty, if only they do not pretend to be registered* practitioners, so long will the public be practically helpless against their machinations; and it goes without saying that the profuse advertisement, paid or unpaid, given by newspapers to the exploits of charlatans enormously increases the mischief.

"CANCER CURES."

IN our issue of Oct. 7th, 1905, p. 1046, we commented upon a quack remedy for cancer called the "Aesiab Cancer Cure," of which we got an analysis. The active ingredient of the cure was tartar emetic. We now learn from the *Cape Times* of March 8th that the proprietor of the nostrum, Mrs. Anna Elizabeth van Niekerk, was prosecuted under Section 35 of Act 34 of 1891, viz., the Medical and Pharmacy Act, for having practised as a medical practitioner. The jury found Mrs. van Niekerk *guilty* and *she* was *sentenced to* pay a fine of £20 or to undergo two months' imprisonment.

A NEW SUTURE FOR THE ABDOMINAL WALL

IN the present issue of THE LANCET, upon p. 967, we print a note upon a new form of suture for use in the abdominal wall which has been introduced by Mr. J. B. Pike of Loughborough. *It is an* attempt to combine the advantages of suturing in layers with the benefits of the single stitch penetrating all the layers of the abdominal wall. The essential point in the stitch is that it passes from one side of the incision to the other as it traverses the different layers. Since it comes to the surface it can be removed completely and so no buried suture remains. Many surgeons appear to meet with much trouble from buried sutures, but other surgeons never, or very rarely, have any trouble with them. It is not improbable that excessive tightness in deep sutures may be the chief cause for these giving rise to trouble, always supposing that no sepsis is present. Mr. *Pike's* suture is *ingenious*, though we think the method has been already described. We can well imagine that it might prove useful in some circumstances.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Hawick News, Standard, Surrey Comet, Surrey Times, Worcester Chronicle, Surrey Advertiser, Morning Advertiser, Tribune, Bradford Observer Budget, Islington Gazette, Cardiff Weekly Mail, Stirling Journal, Times, Daily Telegraph, Daily News, World, Longton Times, Wolverhampton Midland Express, Wigan Observer, Westminster Gazette, Hampshire Advertiser, Southampton Echo, Newcastle Chronicle, Herts Mercury, &c.*

Communications, Letters, &c., have been received from—

A.—Messrs. Anderson, Anderson, and Co., Lond.; Anderson's College Medical School, Glasgow; A. A.; American Medico-Psychological Association, Poughkeepsie, Secretary of; Messrs. W. Anderson and Co., Lond.; A Disgusted Doctor; Dr. S. B. Atkinson, Lond.; An Edinburgh Graduate; Association of Medical Men Receiving Resident Patients, Bournemouth, Hon. Secretary of.

B.—Mr. W. H. Brown, Leeds; Mr. James Boyd, Simonstown, Cape Colony; Mr. H. R. H. Biggs, Lond.; British Druggists, Ltd., Lond.; Messrs. Blackwell, Hayes, and Co., Birmingham; Messrs. Burgoyne, Burbidges, and Co., Lond.; Messrs. S. Bowyer and Co., Lond.; Mr. S. H. Benson, Lond.; Mr. F. D. Byrne, Lond.; Messrs. Baylis, Lewis, and Co., Lond.

C.—Central London Throat and Ear Hospital, Secretary of; Cumberland and Westmoreland Asylum, Carlisle, Secretary of; Messrs. W. Clark and Son, Dunfermline; Country Doctor; Messrs. Cablan and Co., Lond; City of London Hospital for Diseases of the Chest, Lond., Secretary of; Clydebank and District Medical Society, Secretary of; Messrs. C. Comitti and Son, Lond.; Messrs. J. and A. Churchill, Lond.; Dr. A. K. Chalmers, Glasgow; Cheltenham General Hospital, Secretary of; Messrs. Cassell and Co., Lond.; Messrs. Samson Clarke and Co., Lond.; Messrs. Clarke, Son, and Platt, Lond.

D.—Dr. J. W. Dalgliesh, Sutton; Denver Chemical Manufacturing Co., New York; Dental Manufacturing Co., Lond.; Miss Dendy, Withington; D. P.; Dr. Bertrand Dawson, Lond.

E.—Equipoise Couch Co., Ashford.

F.—Mr. Gustav Fischer, Jena; Messrs. Fairchild Bros. and Foster, Lond.; Mr. Charles Fortescue, Torquay; Mr. H. Frowde, Lond.

G.—Mr. J. L. Gilles, Sacramento, U.S.A.; Glasgow University, Secretary of; Mr. F. H Godsell, Lond.; G. B.; Mr. T. H. Gilder, Bournemouth; Guest Hospital, Dudley, Secretary of.

H.—Mr. T. Haas, Bad Kissingen; Mr. A. F. Heald, Lond.; High Shot House, Twickenham, Medical Superintendent of; Mr. H. Hill, Tunbridge Wells; Holloway Sanatorium, Virginia Water, Medical Superintendent of; Dr. F. P. T. Hilliard, Davos Platz.

I.—Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded, Manchester, Secretary of; Invalid Children's Aid Association, Lond., Secretary of; Ingham Infirmary, South Shields, Secretary of.

J.—Messrs. D. Hill Jack and Son, Glasgow.

K.—Mr. C. B. Keetley, Lond.; Dr. James R. Kaye, Wakefield; Dr. Robert Knox, Lond.; Messrs. Kelly and Walsh, Singapore; Mr. Arthur H. J. Keene, Lond.; Messrs. Koidzumi and Co., Kyoto; Dr. J. H. Kellogg, Battle Creek, U.S.A.; Mr. J. Kennish, Lond.; Messrs. R. A. Knight and Co., Lond.

L.—Dr. A. B. F. Lahmeyer, Oporto; *Liverpool* Hospital for Consumption and Diseases of the Chest, Secretary of; Messrs. Lee and Nightingale, Liverpool; Dr. F. Langmead, Lond.

M.—Mr. J. Moxon, Newport, Monmouthshire; Mr Roderick Mackenzie, Esquimalt; Lieutenant J. P. Müller, Lond.; Manchester Royal Infirmary Secretary of; Maltine Manufacturing Co., Lond.; Mr. A. Maloine, Paris; Mr. S. B. Mason, Pontypool; Messrs. C Mitchell and Co., Lond.; Macclesfield General Infirmary, Secretary of; Messrs. Manlove, Alliott, and Co., Nottingham; Manchester Hospital for Consumption, Secretary of.

N.—Dr. J. Niven, Manchester; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

O.—Messrs Ornstien Bros., Lond.; Messrs. Oppenheimer, Son, and Co., Lond.

P.—Mr. Y. J. Pentland, Edinburgh; Messrs. Parke, Davis, and Co., Lond.; Principal, Blackheath; Messrs. Peacock and Hadley, Lond.

Q.—Messrs. Quibell Bros., Newark.

R.—Dr. Robert A. Reid, Boston, Massachusetts; R. G. B.; Royal Southern Hospital, Liverpool, Secretary of; Royal Portsmouth Hospital, Secretary of; Royal Halifax Infirmary, Secretary of; Messrs. B. J. Reid and Co., *Lond.*; *Rebman, Ltd.*, *Lond.*; Messrs. Reynell and Son, Lond.; Mr. W. A. Rees, Lond.

S.—Dr. J. M. Skinner, Aldershot; Dr. D. Lloyd Smith, Frodsham; Mr. J. Sheehan, Lond.; Mr. G. de Ste. Colombe, Bordeaux; Messrs. Saward, Baker and Co., Lond.; Messrs. W. B. Saunders and Co., Philadelphia, U.S.A.; Messrs. Smith, Elder, and Co., Lond.; Dr. E. H. Scholefield, Ravensthorpe; Saarbach's News Exchange, Mainz; Dr. G. H. Skinner, Leith; Messrs J. Smith and Co., Lond.; Scholastic, Clerical, &c., Association, Lond.

T.—*Dr. George Turner, Pretoria*; *Toilet Novelties Co., Bristol*; T. H. B.; Torquay Medical Society, Hon. Secretaries of; Mr. John H. Tonking, Camborne.

U.—University College, Lond., *Principal of.*

V.—Dr. F. Vaz, Oporto.

increased frequency of the beat of the heart may cause it to become quite regular for the time being.[4]

2. The presence of malignant disease[4] in any part may give rise to increased frequency of the pulse-rate without there being any rise of temperature, but upon what this depends is unknown.

3. Affections of the heart, valvular disease, chiefly mitral, some cases of myocardial degeneration, dilatation from causes other than those of valvular lesions, and many of those conditions included under the term "heart strain," may be associated with rapid pulse.

4. Functional disturbance of the heart's action such as may be produced by mental emotions of various kinds, may give rise to increased frequency of the pulse. In hysteria and neurasthenia a frequent pulse is not uncommonly found. In the condition called "paroxysmal tachycardia" sudden attacks of greatly increased frequency of the pulse occur at variable intervals, 200 or more beats per minute being frequently found; after lasting a variable time the attack passes off suddenly. These attacks may occur in persons in whom there can be found no demonstrable lesion of the heart and nothing definite is known as to the cause of these phenomena. Some suppose they depend upon stimulation of the sympathetic, others that they are due to suspension of the inhibitory action of the vagus. Mackenzie[4] thinks that many of these cases are produced by the occurrence of a series of premature systoles of the ventricle, as he has found that in many of such cases he has been able to demonstrate groups of premature systoles, interrupted here and there by beats of a normal character.

5. Exhaustion from whatever cause arising is often accompanied by increased frequency of the pulse; for example, after severe muscular fatigue and in the latter stages of many chronic diseases. In shock and sometimes in the anæmias, especially chlorosis, the pulse may be abnormally frequent.

6. Certain organic nervous diseases are often associated with a pulse of increased frequency; in persons dying from cerebral hæmorrhage, in the terminal stage of meningitis, and in the early stage of locomotor ataxia a rapid pulse is often found to exist, in the first two cases owing most likely to some disturbance of the vagus centre.

7. In exophthalmic goitre tachycardia is one of the cardinal signs and often a very early one. In this disease the pulse-rate is generally over 100 per minute, sometimes 200 or more; in addition, the tension is low and the beats small. Another peculiarity of the pulse in this affection is the extreme variability of its frequency, even within a few seconds; in a case recently under my care its rate would frequently drop from 160 or more beats per minute to the normal within a few seconds and from this patient I have obtained tracings exhibiting bigeminal, trigeminal, and quadrigeminal characters, and two beats of the heart to one at the wrist was frequently to be observed. The fact that the administration to animals of large doses of thyroid substance will cause tachycardia and other symptoms resembling Graves's disease in man[11] tends to show that the rapid pulse met with in this disease may be dependent upon either a diminution or suspension of the inhibitory function of the vagus or an excessive stimulation of the sympathetic, whether this be produced by the circulation in the blood of an excessive amount of the normal thyroid secretion or of some of the products of abnormal activity of this gland.

Abnormally slow pulses.—Slowness of the pulse is only a relative term, since what might be considered slow for one person might be normal for another, both being in perfect health. A pulse of less than 40 beats per minute is of uncommon occurrence, though cases have been described in which only six beats per minute have been observed.[17] In all cases of infrequent pulse it is important to auscultate the heart at the same time as counting the pulse, since many of these cases are due to the fact that the heart at regular or irregular intervals contracts too feebly to cause a wave of pulsation to be felt in the peripheral arteries. What are the pathological conditions giving rise to these pulses? 1. Whatever causes a rise of blood pressure tends to cause a slowing of the pulse-rate; thus, in acute and chronic forms of nephritis and in certain forms of arterio-sclerosis, where a high blood pressure is the rule, the pulse-rate is commonly lowered, possibly a result of stimulation of the vagus centre by the high blood pressure. 2. The retention or accumulation in the body of certain products of an irritant nature; under this heading may be included those cases of infrequent pulses met with in chronic gout, chronic dyspepsia, constipation, jaundice, and also after the excessive use of such cardiac poisons as tobacco. Whilst in some of these cases the way in which the infrequent pulse is produced is unknown, in jaundice, according to Wickham Legg,[12] it arises as a result of the action of the cholalic acid on the ganglia of the heart. 3. Nervous affections. In both functional and organic diseases an infrequent pulse is sometimes observed; thus it may occur in attacks of minor or major epilepsy and in that combination of symptoms the Stokes-Adams's syndrome forms a characteristic feature. In cases in which there is an increase of the intracranial pressure, as in cerebral hæmorrhage, abscess or tumour of the brain, and meningitis with effusion, it is often less frequent than normally, most likely the result of stimulation of the vagus centre in the medulla. That in cases of cerebral tumour the increase of intracranial pressure is the main factor concerned in the production of the infrequent pulse has been shown by the fact that after trephining, and thus diminishing the pressure within the skull it becomes more frequent.[14] In some cases of mental disease, as in melancholia, some cases of general paralysis, and some forms of mania, the pulse is sometimes less frequent than normal, but in what way these diseases and an infrequent pulse are associated is unknown. 4. Exhaustion of the physical or mental powers. In convalescence from prolonged illesses, after recovery from attacks of acute febrile diseases, after severe muscular or mental exertion, in the early stages of shock,[15] and after severe bouts of pain, the pulse is liable to undergo some diminution in rate. 5. Chronic bronchitis and emphysema are stated to give rise to infrequent pulse but how this effect is produced is quite unknown. I have had under my care recently a boy with well-marked emphysema of the lungs and whose pulse was, in the intervals between the attacks of bronchial catarrh from which he frequently suffered, considerably below the normal in rate and generally averaging about 46 beats per minute. 6. In certain degenerative changes in the heart muscle, such as fatty or fibroid changes, a sign which is sometimes but by no means constantly present is diminution of the pulse-rate.

There are three ways in which infrequency may be produced. 1. The heart as a whole may beat at a less frequent rate than it normally should. 2. Some of the ventricular contractions may be too weak to send a wave of pulsation to the peripheral arteries and if these weak contractions occur sufficiently often and at regular intervals we have produced an infrequent, regular pulse. In the case of a woman with mitral disease who had long been under treatment with digitalis for failing compensation I found on several occasions that with an infrequent pulse the heart was beating in couples twice as quickly, the latter beat in each couple being too feeble to cause a pulsation to be felt in the radial artery; this condition disappeared when the digitalis was stopped. In the case of Graves's disease already referred to, although the pulse-rate never fell below normal, yet on many occasions I have found that with a relatively infrequent pulse the heart was beating at double the rate. 3. Although the auricles may beat at a normal rate the ventricle may fail to respond to every auricular contraction; if this occur at varying intervals we obtain an irregular pulse; if at regular intervals and sufficiently often an infrequent pulse results. In a series of recent experimental observations Mackenzie[16] has shown that some cases of bradycardia at least result from this cause and the failure of response of the ventricle to every auricular contraction he considers due to the incomplete recovery of the conducting property of the muscle fibres at the point of union of auricle and ventricle.

Just as there are cases in which the pulse-rate may at varying intervals become very rapid so there are cases in which it may be greatly diminished in frequency—so-called "paroxysmal bradycardia." In a case of this description described by Dr. John Hay,[13] although the pulse at the wrist varied from 17 to 30 beats per minute it was believed that the auricles were contracting much more frequently; on post-mortem examination there was found to be a great thinning of the tissues connecting the auricle to the ventricle. From this it was concluded that the stimulus to ventricular contraction, which normally spreads from the auricle, was unable to pass over this thinned bond of union and having, therefore, to originate in the ventricle itself an infrequent contraction of this chamber and a corresponding pulse were the result.

Pulses of increased tension.—What constitutes normal tension? Every individual has a certain pulse tension which

FIG. 1.

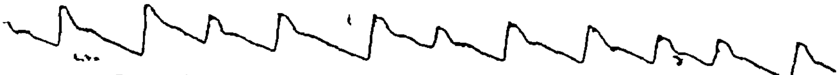
FIG. 12.



Same patient. Irregularity less marked and tension good after rest and treatment.

although normal for the individual in question may not be so for another person and it is only by the examination of a large number of healthy persons and noting the great variations which may occur in the characters of their pulses that any definite idea of the limits of normal tension can be arrived at. Mahomed's[15] rules for the detection of high tension are: (1) in a sphygmogram, if any part of the tracing rise above a line drawn from the apex of the percussion wave to the bottom of the dicrotic notch high tension is present; and (2) if the systolic period of the pulse tracing occupy more than two-fifths of the whole duration of the curve a high-tension pulse exists. Both these rules are very useful, especially from the fact that they admit of easy application. In a well-marked high-tension pulse the following characters may be noticed: the pulse, which may be large or small, according to the force of the ventricular contraction and the relaxation or retraction of the arteries; the vessel feels full between the beats and considerable pressure is required to annihilate the pulsation in it. In a sphygmogram we find the downstroke of the primary wave is generally less abrupt than in a normal tracing, the predicrotic wave is often well marked, especially in renal cases, and the dicrotic notch, sometimes well marked, at other times hardly visible, is high above the base line.

Theoretically, high tension may arise in many different ways; in practice, however, three chief modes are concerned. 1. Increased force of the ventricular contraction, such as occurs during severe muscular exertion; this is of especial importance in cases where the arteries are extensively degenerated, since it may undoubtedly induce rupture of such vessels or favour their yielding. 2. Increase in the volume of blood in the heart or vessels, either indirectly by the absorption of large quantities of fluid from the intestinal tract, or directly by infusion of solutions of various kinds into the vessels, such as is often employed in shock. 3. Increase of the peripheral resistance. This may be induced by spasm of the arterioles of a temporary character, such as occurs during rigors, when the body is exposed to great cold, in migraine, &c. In certain organic diseases a high-tension pulse is a prominent sign; it is usual in acute and chronic Bright's disease, in granular kidney, in chronic gout with which interstitial changes in the kidney are often associated, in some cases of diabetes,[3] angina pectoris, and arterio-sclerosis. In acute Bright's disease at first the arteries are considerably retracted and the pulse feels small; high tension is, however, present almost from the beginning; later, the vessels become larger but high tension continues as long as the disease is in progress, subsiding gradually as recovery occurs. In a sphygmographic tracing the predicrotic wave is generally very well shown and the pulse is somewhat infrequent. In chronic Bright's disease (including the granular kidney), especially the latter, high tension is usually most marked, and in addition there is usually considerable thickening of the coats of the arteries. The cause of the high-tension pulse found in these kidney affections appears to be retraction of the circular muscular fibres of the smaller arteries, resulting from the presence in the blood of bodies of a poisonous nature;[23] that it does not depend upon the changes in the kidney seems probable from the fact that in tuberculous disease of these organs, where large portions of the kidney substance may be destroyed, and in waxy disease high tension is not the rule.[15] In the more chronic cases, however, probably the main factor producing obstruction to the circulation of the blood and a consequent high tension is a general fibrosis of the coats of the small vessels.

In cases where the resistance to the flow of blood through the arterioles is increased by spasm of their muscular coats or by thickening and rigidity of their walls, in order to supply the tissues with an adequate quantity of blood, the force of the ventricular contraction must be increased; when this increase of peripheral resistance is of a temporary nature it is overcome by the utilisation of some of the reserve power which the cardiac muscle normally possesses; when the increase is more permanent the reserve power of the heart is unable to cope with the increased amount of work thrown upon this organ; to do this the power of the heart must be absolutely increased and this is brought about by hypertrophy of its muscular walls. By these means the circulation is efficiently maintained and the blood pressure is kept high; ultimately, however, either from an increasing obstruction to the blood-flow through the smaller arteries or to the limits of cardiac hypertrophy having been reached, disturbance of this perfect compensation arises, the heart muscle yields, dilatation sets in, the blood pressure falls, and the circulation is no longer efficient.

In pregnancy the pulse tension is raised[26] and here cardiac hypertrophy, increase in the volume of the blood, and pos- sibly the retention of effete matters in the blood, may al assist in its production. In some cases of anæmia, especially in the "secondary" anæmias and in certain cases of angin pectoris, high tension is present, in the latter often a result o general arteriole spasm.

Pulses of low arterial pressure.—In a well-marked case o low arterial pressure the pulse assumes the following characters: both the impact of the pulse wave and it subsidence are sudden; when the arterial pressure is very lo the finger may feel merely a slight tap as the pulse wav passes[4]; between the beats the vessel feels empty. Th condition of the dicrotic wave varies. In some cases it i very well marked and may be almost as large as the primar wave; at other times, especially in those cases in which th arterial pressure is very low, it may be scarcely discernible the bottom of the dicrotic notch is close to the base line o the tracing and the predicrotic wave is either absent or il defined.

As with pulses of high tension, there are three chie factors concerned, either single or together, in the pr duction of low arterial pressure. First, feebleness of con traction of the heart. Amongst the various condition giving rise to this may be mentioned exhaustion of th general physical tone in whatever way produced, prolonge fever and the action of toxins of bacterial origin, such a may arise in acute febrile diseases, and degeneration of th muscular tissue of the heart or dilatation of its chamber the ultimate effect of all of which is to lessen the power o the heart. Secondly, diminution of the volume of blood i the heart and vessels. Loss of large quantities of blood, a for example, during surgical operations, and draining away o large quantities of liquid from the body, such as occurs i prolonged vomiting or diarrhœa, may all help in producin low arterial pressure. Thirdly, diminution of the per pheral resistance by dilatation of the arterioles. I fever such a condition is present and the tension of pulse originally high may on the occurrence of an acut febrile process be much lowered, though whether or no any serious diminution of arterial pressure may in thes cases be brought about by such means is doubtful. I shock the low arterial pressure found has been considered t be due to a vaso-motor exhaustion[19] and a relaxation of th peripheral vessels; on the other hand, it has been argue that there is no relaxation but an actual contraction of th arterioles in shock and that the low blood pressure whic arises is produced by a later relaxation of the vessels of th internal parts.[23]

It may here be mentioned that high and low tension pul are, after all, only relative terms—one person may hav habitually a pulse of high pressure and another one of lo pressure and yet both may be in perfect health. The limits o normal tension are wide and when in A the tension is foun to be high and in B low due consideration must be allowe for individual variations, and unless the diminution or i crease in arterial pressure be marked probably not muc importance should be attached to these variations unle other indications of disease appear.

Pulse irregularity.—Mackenzie[4] divides pulse irreg larities into two varieties: first, the youthful form, i which the systolic period of the pulsations is quite regul but in which the length of the diastolic periods varies; thi he finds, occurs in some cases of slowing of the pulse aft infancy and after febrile diseases; and, secondly, the adu form of irregularity, in which premature systoles of th ventricle occur, and according to the number and times o occurrence of these imperfect ventricular contractions man different forms of pulse irregularity are to be met with. a premature systole occurs soon after every full beat an is followed by a pause we have produced the "puls bigeminus," a form not uncommonly found in cases o mitral disease and as an effect of the action of digitalis. is also said to be frequently present in those cases of musc failure of the left ventricle, from whatever cause arising. When two premature systoles occur after every full beat w have produced the "pulsus trigeminus," when three th "pulsus quadrigeminus," and according to the time o occurrence of these premature ventricular contractions man different forms of pulse irregularity may appear.

Amongst the numerous causes of irregularity may b mentioned nervous excitement, palpitation of the heart, an exhaustion of the physical or mental powers; pressure upon, or displacement of, the heart, as may occur in cases of flatulent distension of the stomach or intestines is also said to be a cause of pulse irregularity. I am rather sceptical of this mode of origin of irregular heart action, as in many cases of pleural effusion or ascites where pressure upon, or displacement of, the heart may be marked the heart does not often become irregular unless other conditions exist which may produce it. The excessive use of such articles as tea, coffee, and tobacco may cause an irregular pulse.

In a state of health the respiratory movements have no definite influence in affecting the character of the pulse-tracings. In some cases of disease where there is an interference with the free entry of air into the lungs during inspiration the beats become small, to increase again in size with expiration; I have found such a pulse in a case of pneumonia complicating subacute rheumatism. In the pulsus paradoxus this diminution in the size of the pulsations during inspiration becomes very marked and the pulsations may even disappear during inspiration; at one time supposed to arise as a result of a constriction of the aorta by fibrous bands, which during inspiration might constrict the lumen of this vessel, such an explanation will not suffice, as this kind of pulse has been found in other conditions which by themselves could not act in this way. It has been found in cases of chronic mediastinitis, of which it is supposed to be an important sign, in cases of mediastinal tumour, in mitral incompetence with dilatation of the heart, and in other conditions. It has been found in one radial only.[1] At present we do not know in what way it is produced.

As a more or less permanent condition pulse irregularity occurs in valvular disease of the heart, especially in mitral lesions, in degenerative changes in the heart muscle, in dilatation, and in some cases of meningitis. The pulse irregularity which is common in the later stages of mitral disease Mackenzie[1] thinks is due to a partial paralysis of the left auricle; from this results an irregular discharge of blood from this chamber, irregular stimulation of the ventricle, and consequently an irregular pulse.

In some cases of irregular pulse the whole heart participates in the irregular action; in others the irregularity is apparently confined to the ventricle. In a recent paper Mackenzie[2] has shown that he has experimentally been able to verify the statement of Wenckebach, that when one of the functions of the heart muscle is depressed an irregularity peculiar to this function would be found. He investigated the condition of, conduction of the muscle fibres between the auricle and ventricle and he did this by taking tracings from the jugular vein (which show auricular and carotid pulses) and comparing them with tracings from the radial artery taken at the same time. The period of time intervening between the commencement of the auricular contraction and the carotid beat, which normally occupies one-fifth of a second, he finds may be increased without there necessarily arising irregularity of the pulse. In some cases, however, of irregular pulse he has found that this interval of time may be progressively increased, and indicating, as it does, a depression of conductivity of the muscle union between auricle and ventricle, the stimulus to contraction may at times be unable to pass over from auricle to ventricle and a missed beat results. If this depression of conductivity occurs at regular intervals the ventricle may fail to respond to every auricular contraction and a slow pulse may result.

Lastly, pulse irregularity is said to occur in some persons who are apparently in perfect health and in whom no cause for this abnormality can be found.

The pulse in cardiac disease.—With the exception perhaps of aortic regurgitation, there is no disease of the heart which can be said to give a pulse in any way characteristic of the morbid lesion. The typical pulse of incompetence of the aortic valves is one which arises and subsides suddenly—the so-called water-hammer pulse. In a sphygmogram we find a sudden and generally large upstroke followed by a rapid fall, these characters depending upon a great and sudden increase of pressure in the artery produced by the hypertrophied ventricle and the sudden lowering of arterial pressure, the result of the regurgitation back into the ventricle of a quantity of blood which normally should be propelled on into the distal vessels. The dicrotic wave varies. When the regurgitation is marked this wave may be almost or entirely absent; with less regurgitation it may be well shown. Broadbent[3] says that the pulse in this disease depends a good deal upon its mode of origin; if arising from endocarditis characters already noted; if due to atheroma and associated with aortitis deformans, although the wave arises and subsides quickly, there is no real collapse. It seems to me that these differences depend upon the presence or absence of stenosis of the aortic orifice; if stenosis be absent, as it may be in those cases resulting from endocarditis, the pulse will be of the water-hammer type; if, on the other hand, stenosis be present, then the up and down strokes of the pulse tracings will be much less abrupt, the collapsing character will be much less marked, and the summit of the primary wave will be more rounded.

In stenosis of the aortic orifice the pulse wave arises in a slow, deliberate way, the narrowing of the orifice preventing the full effect of the ventricular contraction being felt at once in the aorta[4]; in a sphygmogram we find a sloping upstroke with a broad summit; there is not the sudden subsidence of the wave as in the previous condition. It is in this form of valvular lesion that "anacrotic" tracings are commonly found to occur; they are, however, not characteristic of this affection. In some cases the apex of the primary wave is divided into two parts constituting the "pulsus bisferiens," the mode of production of which is doubtful, some thinking it indicates that the ventricle contracts in two stages, others that it is an artificial production.[5] In one case reported it was found on one side only and no definite cause for this unilateral condition was found.[6]

In mitral disease, either stenosis or regurgitation, the pulse exhibits no special characteristics. Theoretically, one might suppose that in stenosis the pulse would be small, but this is by no means the rule. In both forms of valvular defect, when compensation is well maintained the pulse may be quite normal in character. In the later stages, with excessive dilatation of the left auricle, it tends to become rapid and to exhibit marked irregularity in both size and time; the tension, also, in the later stages is apt to become very low.

Dilatation of the heart from other causes than those of valvular defects brings with it no characteristic changes in the pulse, any changes that may be found depending upon the side of the organ affected and on the cause giving rise to the dilatation.

The pulse in aneurysm.—In cases of aneurysm of the aorta involving that portion of the arch between the origins of the innominate and the left subclavian arteries, important differences may be found in the pulses in the two radial arteries, these differences depending upon compression of the left subclavian by the aneurysmal sac or by obstruction of its lumen by blood clot or narrowing of its orifice by atheromatous changes, and unless some such obstruction exist no difference in the two radial pulses may be found.[7] Compression of a vessel by tumours may produce exactly similar alterations of the pulse as are produced by aneurysm. As a result of the obstruction to the flow of blood along a vessel affected in any of these ways, the pulsation in the vessel beyond the obstruction appears more gradually and reaches its maximum more slowly than that in the corresponding vessel of the opposite side. In a sphygmographic tracing this is well seen, and further, such a tracing shows a rounded summit and a downstroke almost or entirely devoid of secondary waves. In some cases this obstruction of the lumen of the vessel may be so marked as almost to annihilate pulsation in it; this was well shown in a case I had recently the opportunity of examining. The patient, a man, aged 55 years, with the physical signs of aortic regurgitation, developed inequality of the radial pulses, the left being smaller and exhibiting a tracing indicative of obstruction to the free passage of blood into it. On the day preceding death the pulsation in this vessel could hardly be distinguished, that in the right radial remaining large and of its usual characters. On post-mortem examination, a fusiform aneurysm was found involving the aorta, extending from the origin of the left subclavian to a point about two and a half inches beyond. On opening up the aneurysmal sac, which contained some partly organised clot, the orifice of the left subclavian artery was found to be almost entirely obstructed by clot, removal of which showed an orifice just large enough to admit a probe.

Is there delay of the pulse in the vessel beyond an aneurysm? Certainly, from digital examination of the radial arteries in a case such as the one I have already described and a comparison of them, one gets the impression that there is. Mackenzie, however, thinks this delay is apparent only and that it is due to the fact that in the vessel beyond the aneurysm the maximum force of the beat is not attained so suddenly as in the corresponding vessel of the opposite side. Further, he has shown that in aortic regurgitation, in which the pulse has been supposed to be delayed, such is not the case. By comparing tracings obtained from the apex beat and radial artery of patients suffering from this disease with similar tracings obtained from persons in whom there was no disease of the heart, he has found that the period of time intervening between the apex beat and the radial artery pulsation, is the same in both.

Conclusions.

The arterial pulse represents in the main the sudden increase of pressure occurring in the arteries as a result of the ejection into them of the contents of the left ventricle, and it travels from the heart to the peripheral parts in the form of a wave, diminishing in size as it passes along. The pulse curve represents the changes occurring within the artery at the part under examination. We have seen that its form varies according to the force of the contraction of the ventricle, to the blood pressure, to the condition of the vessel wall, and to the distance of the vessel from the heart. This sudden increase of pressure in the arteries having reached its maximum is followed by a fall, the fall, however, being interrupted by a slight increase of pressure as the dicrotic wave appears; it then returns to the normal.

We have seen that the dicrotic wave, whilst not capable of being fully explained, still appears to arise as a positive wave from the closed aortic valves; of the other secondary waves we know very little about their modes of origin. Further, we have seen that the factors concerned in the regulation of the normal pulse, and disturbance of which may cause the pulse to assume various forms of abnormality, are the integrity of the heart muscle and maintenance of its functions, the condition of the vessel walls, the state of the arterioles and the nervous mechanism regulating and controlling the heart beat, and the state of contraction or relaxation of the circular muscular fibres of the arterioles In some forms of abnormal pulses the channel by means of which such abnormality is brought about is evident; in others we have to rely on conjecture.

Of pathological pulses few, if any, are characteristic of the diseases producing them; in the large majority of cases no specific alterations are produced.

Of alterations in the tension it is in arteries which are either naturally small or are abnormally retracted that one is apt to overlook high tension, and I think that in such cases as these the sphygmograph is especially useful, since it may demonstrate high tension hardly appreciable to the finger.

In some cases of disease the pulse affords us valuable assistance in prognosis; it often indicates the necessity for the exhibition or withdrawal of drugs and affords us commonly a guide to the rational treatment of many diseases associated with circulatory disturbances, and upon our ability to recognise the indications for treatment derived from our examination may the success of our efforts rest.

In these few remarks I have endeavoured to set forth some of the prevailing ideas as to the nature of the arterial pulse both in health and disease, illustrating my remarks by reference to a few of my cases which have shown any special peculiarity. I have, wherever possible, taken sphygmographic tracings from patients whom I have been able to keep under observation for some time and some of them I exhibit this evening.

[Over 60 sphygmographic tracings, illustrating different forms of pulses, were shown during the lecture.]

A Clinical Lecture

ON

THE "ACUTE ABDOMEN."

Delivered at St. Thomas's Hospital on March 1st, 1906,

By WILLIAM HENRY BATTLE, F.R.C.S. Eng.,
SURGEON TO THE HOSPITAL.

Gentlemen,—When the third lecture of this series[1] had been given and the largest part of the subject considered to which the term "acute abdomen" has been applied, it seemed that a group of cases in which disease of the female pelvic organs plays no inconsiderable a part would have to be omitted. This might appear of slight moment, for these conditions are dealt with in the lectures given by my colleagues in the department for diseases of women, but the more urgent complications of these diseases come under care in the surgical wards, usually without the formation of a diagnosis. The "acute abdomen" may arise from a pyosalpinx, the bursting of the sac of an ectopic gestation, the acute necrosis of a fibroid of the uterus, the twisting of the pedicle of an ovarian cyst, or the rupture of the cyst into the general peritoneal cavity. To-day I wish to bring to your notice the account of a patient who was recently admitted for acute abdominal symptoms due to a ruptured pyosalpinx and afterwards remind some of you of other cases formerly under treatment in my wards which show when it is necessary to explore the abdomen after the onset of symptoms due to pelvic mischief which has become acute. There is a certain amount of similarity in the symptoms caused by a ruptured pyosalpinx and those due to a ruptured ectopic gestation, and it is to a consideration of the more acute abdominal complications of these affections that I wish to limit my observations to-day.

The account of the case to which I have already referred is that of a patient who is under treatment in the Beatrice Ward. She is a woman, aged 21 years, who was admitted under the care of Dr. H. W. G. Mackenzie on Feb. 20th, 1906, early in the afternoon. The history of the case was that she had been suddenly seized with abdominal pain during the night of the 19th. This pain had been very severe, had been in the upper part of the abdomen, and she had vomited. She had had a meal of pork during the previous evening. At 4 o'clock in the morning a medical man was sent for who gave her some medicine which she vomited. In her previous history there was an account of indigestion of indefinite character some years ago. There had been a profuse vaginal discharge for some months and the menstrual period was a fortnight overdue. There had been no action of the bowels for two days.

When seen in consultation with Dr. Mackenzie late in the afternoon the patient was lying on her back looking very ill and anæmic and seemed collapsed, drowsy, and apathetic. There was a small circular flush on each cheek. The skin was dry. The respirations were somewhat quickened (24) and the pulse was 110. The temperature was 101 4° F. She complained of pain in the abdomen. This was found to be moving quite well in the upper half but was less mobile than usual in the lower part. On palpation it was quite soft all over but there was much complaint of tenderness, especially in the iliac region and right side up towards the liver. Nothing abnormal was found, the abdominal wall being quite without rigidity or even resistance of muscle to palpation. On percussion the note over the whole abdomen was normal. The liver dulness was normal. At 5 30 abdominal exploration was carried out, an incision was first made in the epigastric region and the stomach and duodenum closely examined. The hand was then passed downwards to the iliac fossa and appendix region and onwards to the pelvic organs. A tumour was felt to the left of the uterus. This was recognised as a pyosalpinx and it was thought that a rupture of this would account for the condition. A second incision was made in the middle line above the pubes and when the peritoneum was opened free, thin, somewhat viscid, odourless pus was found extending from the pelvis into the flanks. The intestines were packed off with strips of sterilised gauze and the pyosalpinx was removed after the application of three (No. 4) silk ligatures. There was no inflammation of the peritoneal coat of the intestine and no lymph was seen. The area of infection was cleansed with moistened sponges and drainage was provided by a red rubber tube and a strip of gauze. The right ovary was somewhat fixed by adhesions which were freed, but appeared to be healthy, as did also the tube on that side. The upper wound was sutured in layers by Mr. J. H. Bletsoe, the house surgeon, whilst the pelvic condition was being treated. The pyosalpinx formed a tumour of the size of a hen's egg, the walls of the Fallopian tube were much thickened, and there had been a rupture of the tube not far from the ostium abdominale, which itself had been closed by adhesion to the broad ligament. The ovary formed part of the inflammatory mass removed and could only be distinguished on dissection. The plug was removed on the 24th; there was a small amount of discharge which was quite clear. The bowels acted twice and she was doing well. The pulse was 76 and the temperature was normal or subnormal; since the operation pain was quite relieved. (This patient continued to progress satisfactorily and left the hospital on March 13th.)

---

[1] The previous lectures were published in The Lancet of Jan. 27th (p. 201) and Feb. 3rd (p. 273) and 17th (p. 429), 1906, respectively.

Pyosalpinx is recognised as the most important condition giving rise to peritonitis having its origin in the pelvis, repeated localised attacks being common. As a source of diffuse spreading peritonitis it is less common, for the thickened tube does not often rupture as it did in this case and allow the purulent contents to spread into the general cavity of the peritoneum. There can be little doubt that the gonococcus is extensively diffused by the rupture of the tube and although Mr. Leonard S. Dudgeon and Mr. P. W. G. Sargent[2] conclude that it possesses a slight pathogenicity when introduced into the peritoneal cavity, it does produce a peritonitis which may be ultimately fatal. We must endeavour to operate before peritonitis sets in; the prognosis is thereby much improved and the duration and severity of the illness are diminished.

None of those who saw the extent to which purulent diffusion had taken place in this patient doubted that diffuse peritonitis must have ensued had operation been delayed. It was the aspect of severe illness with the history that induced Dr. Mackenzie to suggest the desirability of exploration, for local signs of the gravity of the attack were absent. There was no trace of protective rigidity of muscle, whilst the tenderness found was not in any way remarkable. Nothing indicated the probable origin of the symptoms, and although the epigastric region was explored this was in deference to the history of former indigestion, with a recent heavy meal, rather than to any idea that stomach ulceration had really given way, for there were no localising signs. I have stated that the appendages on the right side appeared to be healthy and were therefore not removed; it was probably right to leave them but the result of so doing in a case formerly under my care in which a pyosalpinx had given rise to intestinal obstruction has made me less confident of this than I might otherwise have been. The appendages on the left side appeared normal and were therefore left, but the woman returned with septic peritonitis, the result of a rupture of the tube, in the following year.

A woman, aged 28 years, was admitted under the care of Dr. Mackenzie on Jan. 31st, 1903. She stated that she had been quite well until the 25th when she was taken ill with pains all over her. The attack passed off but came on more severely at 4 A.M. of the 25th and was accompanied by severe pain in the right hip which spread all over her abdomen. On admission the abdomen was distended and did not move well on respiration and the patient looked ill. The abdomen was not tender; it was easy to examine but nothing abnormal was detected on palpation. Examination per rectum showed nothing unusual. The temperature was 100·6° F. and the pulse was 104. On Feb. 3rd she had an attack of abdominal pain with vomiting, there being visible distension of small intestine and peristalsis. The bowels acted well just before the attack. Operation was advised because it was recognised that she had recurring attacks of obstruction due to a mechanical condition, but she refused until Feb. 6th when another rather more severe attack of pain and vomiting induced her to think more seriously of her illness and give her consent.

Incision was made through the right rectus sheath and the muscle was temporarily displaced. On opening the peritoneum a coil of small intestine was found to be distended and to pass down into the pelvis which seemed strangely full. At first it appeared as if the uterus was very large and smooth-walled, but further examination showed the swelling to consist of two parts, a softer one to the right, and when the finger was passed into Douglas's pouch a groove could be felt marking a division between them. The pelvis was packed off with sponges and a large pyosalpinx, which ruptured during the process, was brought outside, separated from its attachments, and removed. The pus was very offensive. The ovary was lost in the mass removed. The left side appeared to be normal. The loop of obstructed gut was found adherent to part of the boundary wall of the pyosalpinx which had been left behind—it was kinked from before backwards; another loop also adhered to this part but was not obstructed. These were freed and some omental adhesions were also separated or divided between ligatures. The pelvis and lower abdomen were carefully washed out with warm saline solution and a tube was left in which extended into Douglas's pouch. On the third day some distension of the stomach was present and this was followed by a more or less general meteorism which very gradually subsided under appropriate treatment, although the patient was for a time seriously ill. The tube was removed on the seventh day after operation. She left the hospital on March 14th, 1903.

On Oct. 23th, 1903, the patient was re-admitted to the same ward with symptoms of diffuse peritonitis. She had enjoyed good health since leaving the hospital until three weeks before her return; she then had a menstrual period, followed a week later by hæmorrhage from the vagina which lasted for three or four days. This was followed by acute pain on the right side of the abdomen which spread to the left side. This pain continued for a week and then for the three days previous to her coming up it increased considerably and was again accompanied on the first and third days by hæmorrhage. She had vomited four times on the day of admission but not before. The abdomen was slightly distended but scarcely moved with respiration. The left rectus was rigid and the lower half of the left side. Great tenderness was complained of all over the abdomen. The flanks were resonant. The pulse was 120 and the temperature was 102° F. A tender swelling could be felt per vaginam in the left fornix. Mr. Percy Sargent, who operated, found that the pelvis contained pus, whilst a sero-purulent fluid invaded the lower abdomen. The Fallopian tube was of the size of a thumb; its walls were much thickened and it was distended with pus. The ovary contained a large cyst in which was a blood clot of the size of a Tangerine orange. The lower abdomen was washed out with saline solution. From the history of disturbed *menstrual* function it was thought that the blood clot might represent the remains of an ovarian gestation but careful examination in the clinical laboratory did not confirm this idea. The case was essentially one of peritonitis with much purulent effusion without any hæmorrhage. The patient made a good recovery.

Another part of this subject—that of ectopic gestation and its rupture as a cause of the "acute abdomen"—introduces us to additional symptoms: those caused by the increasing accumulation of blood in the peritoneum and the effect of its loss from the circulation on the general state of the patient. The rapidity with which it is poured out and the effect of this are sometimes so great that the patient dies as suddenly as if a deadly poison had been taken. Luckily, most of the victims of this accident are not so quickly overwhelmed and time is given for attempts at a rescue. It is not my intention to enter into a discussion of extra uterine gestation, its varieties, diagnosis, modes of ending, &c., but simply to introduce the subject as it occurs in actual practice as a surgical emergency, so that you may be able to recognise and successfully to treat it. Of the more severe cases of hæmorrhage I have selected one of rupture of a sac situated in the wall of the uterus in which the symptoms were (as they usually are) very marked and the general state of the patient was a somewhat desperate one. It is a rare position for the sac to occupy, but there is no means of ascertaining this in any case before the abdomen is opened, but the indications for operation are the same as in examples of the much commoner accident—rupture of a tubal gestation.

A married woman, aged 35 years, was admitted under the care of Dr. Mackenzie on April 23rd, 1903, on account of acute abdominal symptoms. Her history was as follows. She was treated in a London hospital nine years before for "peritonitis" after a confinement. About a month previously she began to suffer from attacks of vomiting which came on especially after food, which she was unable to retain. There was also some indefinite pain in the abdomen. A fortnight previously she attended the out-patient department and was treated for gastritis. The abdominal pain got worse and at 4 o'clock on the day of admission she had a very severe attack which doubled her up and later completely prostrated her. She vomited several times and became very pale, cold, and collapsed. During the afternoon she fainted. She was brought to the hospital 13 hours after the onset of the severe pain. She had had five children, four of whom were still living—one died at the age of six years. The youngest was 18 months old. The last menstrual period was six weeks previously; one should have come on about a week before admission. She had always suffered from leucorrhœa, but during the past few weeks she had been worse than ever. On admission she was blanched, emaciated, and in a state of collapse. The abdomen was held rather rigidly and was generally tender, especially in the lower part. In the left iliac region there was a rounded elastic swelling and there appeared to be fluid in the lower part of the abdomen and to a less extent in the flanks. The pulse was 120 and feeble, the respirations were 26 and sighing, and the temperature was 97·2° F. At 8 P.M. a median incision in the lower abdomen about four inches in length was made and the dark colour of the blood could be seen before the peritoneum was incised. When the abdominal cavity was opened there was an immediate gush of blood mixed with clots and the hand was at once passed to the uterus and tubes. The left one was felt to be enlarged and so was brought to the surface. The enlargement was found, however, to be due to a hydrosalpinx, so the uterus and right tube were drawn up for inspection. The uterus was ruptured at a point on the fundus to the inner side of the place where the right tube joined it. The uterus was longer than normal; the opening was about one and a half inches in length and placed transversely. From it there protruded a fluffy mass of delicate moss-like tissue which filled the opening and bulged over the edges. From this place there was a constant oozing of blood. This was evidently placental tissue. It was removed with a curette and the cavity from which it came was scraped out. The opening was then closed with a continuous Lembert suture. This apparently arrested all bleeding. The left tube was then removed and the pedicle was ligatured with silk. The intestines appeared pale, almost bloodless, and contracted. The peritoneal cavity was carefully cleansed of all clots and free blood by saline irrigation and sponging, after which the abdomen was closed. Four pints of saline infusion were injected into the left median basilic vein during the operation with evident benefit. The patient slowly recovered from the shock of the operation and the large loss of blood. On the third day she complained of abdominal distension and pain in the epigastric region due to acute dilatation of the stomach, for which the stomach-tube was employed with lavage. Some distension of the abdomen continued for about three days but the temperature continued normal and the pulse about 100. Convalescence was slow and she did not leave the hospital until June 29th.

---

[2] The Bacteriology of Peritonitis, p. 33.

In another case of extra-uterine gestation the diagnosis was rendered difficult because of the history of the illness and the absence of clotting in the blood which had escaped into the peritoneum.

A woman, aged 31 years, was admitted to St. Thomas's Hospital on April 14th, 1904. There was a history of irregular periods and a white discharge on and off between the periods, but general good health until April 8th. She was then seized with a severe internal pain which was so bad that on the following day she was obliged to go to bed; it improved but returned again severely on the 12th. It was most marked on the right side, running up to the right breast and affected the right leg so that it was very painful to move. This pain started with the period which was a fortnight overdue. When the discharge stopped the pain left her but came on again when it returned. She was almost fainting on arrival. On admission she was a pale anæmic woman. The abdomen was slightly distended and tender and it was difficult to examine satisfactorily as she held herself very rigidly. There appeared, however, to be more dulness in the right flank than in the left. On vaginal examination the uterus was found to be normal and freely moveable and a little retroverted; there was no fulness in Douglas's pouch or abnormality of the uterine appendages. The tongue was furred but the bowels were acting. The pulse was 112 and the temperature was 99° F. On the 18th she was again seized with pain in the right iliac region. The vaginal discharge recommenced, being of a red colour. She felt very faint. The pain passed off during the night and on the next morning her temperature was 100·2° and on the following evening 101°. The history, character, and duration of the pain, with the rise of temperature, made it very probable that the appendix was diseased whilst the account of the menstrual irregularities induced Dr. W. W. H. Tate to suggest the possibility of an extra-uterine gestation which was leaking into the peritoneum as a result of some rupture of the sac. On the 29th the operation by temporary displacement of the rectus was performed and a diseased appendix removed after the application of the clamp. As free blood was present in the peritoneum when it was opened and there was none in the pelvis the opinion expressed by Dr. Tate was confirmed and rapid incision in the median line low down gave access to the pelvic organs. The right tube was thickened at one part and from the ostium abdominale hæmorrhage was still proceeding. This was ligatured and removed with the ovary. A tumour of about the size and shape of a pigeon's egg was attached to the left broad ligament. This was excised and proved to be an intra-ligamentous cyst with papillomatous growth inside it. The appendix was catarrhal and was strictured near its base. The right Fallopian tube was enlarged and thickened, the ostium abdominale admitted a little finger, and its mucous membrane was rugose. The uterine end of the tube for a distance of one inch was normal; beyond this it was dilated and contained a large clot which was attached to the upper and posterior part of the interior. No fœtus was found. The right ovary was cystic and contained a recent corpus luteum, besides several old ones. A pedunculated cyst containing blood-stained fluid was attached to the right broad ligament. The incisions in the abdominal wall were closed without drainage after the pelvis had been sponged and flushed with warm saline solution. A week later she complained of pain in the left side of the pelvis and a hæmatocele gradually formed and suppurated, being opened per vaginam about three weeks after the operation. She left hospital quite recovered on June 4th, 1904.

This was, then, a case of tubal abortion, the loss of blood coming from the open mouth of the tube, whilst the unusual character of the pain was explained by the condition of the appendix. There was no sudden seizure as in the patient with intramural gestation, but the result would have been fatal ultimately and I have quoted it as a contrast to the former. In all these cases of operation for hæmorrhage the uterine appendages should be at once examined and if anything abnormal is found brought out of the wound. No attempt to clear away blood clot must be permitted until the source of hæmorrhage is found and its flow arrested. Examine both sides, for there may be a ruptured sac in each tube. As a temporary measure it is advisable to apply clamps to the uterine end of the tube and to the broad ligament beyond.

The sudden onset of an appendix suppuration may simulate the bursting of the sac of an extra-uterine gestation, if there are menstrual irregularity and no marked rise of temperature. A sudden access of symptoms due to bursting of the abscess with collapse simulates a similar condition with renewed hæmorrhage. Some three years ago I was called upon to go into the country at night to see a lady with an acute abdominal illness. *The history* was that *ten* days before when the period was a week overdue she had had a severe attack of abdominal pain with faintness and sickness, from which she had gradually rallied. This had been regarded by her medical attendant as probably due to a rupture of an extra-uterine gestation, but as she slowly improved he did not think that operative interference was called for. On the morning before I saw her she had been again suddenly seized with a similar attack of abdominal pain and became collapsed. The condition of collapse continued when I arrived and was extreme. The pulse was imperceptible, the temperature was subnormal, the extremities were cold, and the patient was restless. On the following morning the condition was not improved and, in fact, for four days she was so ill that it was not thought worth while to take her temperature. As a result of careful tending she recovered so that on the seventh day after I had first seen her it was possible to open a large collection of pus which had been present for the week without much increase in size. There was no blood clot in this and although the appendix could not be found it was regarded as the probable cause for the suppuration. During the closing of the abscess an extension of it to the left of the umbilicus was especially slow in recovering and pus could be expressed from this part when everywhere else the condition appeared satisfactory. At this point adhesions formed between coils of small intestine and I operated for acute intestinal obstruction due to them later in the year. Still later in the same year an attack of appendicitis made it advisable to remove the appendix. The patient has enjoyed good health since.

VACCINE TREATMENT IN SURGERY.[1]

BY H. M. W. GRAY, M.B., C.M. ABERD., F.R.C.S. EDIN.,
SURGEON TO ABERDEEN ROYAL INFIRMARY.

IT is fitting that evidence on the effects of new methods of treatment should be heard from many sides before such are extolled or condemned. Still better is it that such methods should be tried personally if the principles on which they depend are shown by sensible and reliable workers to satisfy a scientific conscience. About two years ago I heard such evidence with regard to vaccine treatment, founded on Professor A. E. Wright's excellent investigations, and, being satisfied with the authority, have during the past 18 months endeavoured to test such treatment clinically in as fair a way as I could. Hence I have ventured to appear before you to-night to record my experience. I wish to lay facts before you and therefore, where possible, I have had my statements verified by others who have seen the cases. Before putting these facts before you it may be well once again to run over the principles underlying the method of treatment.

By vaccine treatment is meant, roughly, the injection into the patient of quantities of the organisms (dead) which produce the disease. It is found that the resisting power of an individual against the specific organism can be raised with safety by such means. In chronic localised infections or even in some general infections of a chronic character—e.g., Malta fever—sufficient stimulus to successful resistance is wanting. To use such a vaccine during an acute disease would be simply adding fuel to the fire. After such vaccine is injected there is produced a depression in the resisting power—a negative phase—which lasts for a variable time according to the amount or virulence of the vaccine. Following on the negative phase the resistance rises till it is in most cases above what it was before—a positive phase. By repetition of such doses at suitable intervals a cumulative positive phase is usually obtained, so that resistance is much increased. If, however, a second injection is made during the negative phase, this phase is augmented so that harm is done. Hence the necessity to estimate the opsonic power of the patient's serum, which forms a convenient indication of the resisting power, to know when the positive phase is well developed, as then is the time to give another dose. I wish to indicate at this point that if the cycle of events following the injection of a specific vaccine has been estimated a sufficient number of times in different individuals so that one knows the average time required for the positive phase to develop fully, in my opinion it is unnecessary to estimate the opsonic index in most cases. On this idea I have worked for the past seven months and I think it a matter of importance that my results have not suffered therefrom.

Tuberculous disease in its various phases has provided the most frequent test for the efficacy of vaccine treatment. Koch's tuberculin R. differs from the other vaccines used in that the most soluble constituents of the culture are abstracted from it. I have always employed that supplied by Meister Lucius and Brüning, Höchst, Germany. For brevity I shall call it hereafter T.R. It will best serve the purpose to describe the effects of T.R. treatment on the different lesions.

Tuberculous glands.—If these are simply enlarged—not broken down, caseating, or calcified—in every case I have found that the glands disappear after a very few injections of T.R.; in quite early cases no trace of enlargement remains after even only two or three injections. This has been my experience in three cases. One must bear in mind that a surgeon does not usually get such early cases, hence my experience is limited. It is probably impossible to say at first whether caseation has occurred in any given gland, but if the gland, of consistence usual in such cases, has not decreased in size markedly after from six to eight weeks' treatment I have always suspected caseation and at operation this condition has been found. In many of the cases one could compare two or more glands of apparently equal size and consistence. During treatment one or more would so decrease in size as to be impalpable, while the caseating ones would decrease only to a slight extent. If periadenitis, with consequent matting and tenderness, had occurred this usually speedily cleared up. The tenderness disappeared and the glands became more defined and moveable, then smaller in size. If caseation has occurred, operate. Operation need not be vigorous. I have such faith in T.R. that I am going back from my previous attitude in the treatment of tuberculous glands. I used to think that thorough excision, where possible, of all tuberculous foci was the only rational treatment. Now I find that in, e.g., *isolated* caseating glands gentle scooping out of the caseating core is sufficient. If a depressed cicatrix results this may be excised by a very small incision under a local anæsthetic at a later date when the patient is quite sound. If a *mass* of caseating glands exists then excise *en masse* in the usual way. Somewhat similar remarks apply to broken-down fluctuating glands. At first I tested the capabilities of T.R. to cause absorption of the fluid material but in no case did it succeed, although in all the "abscesses" became more circumscribed. If tenderness were present it disappeared and if redness of the skin were present over the gland this lessened or disappeared also. Had fluid been absorbed the condition left would have been at best similar to that in the caseating gland. Hence I think it is waste of time to delay operation long in such cases. In one case I aspirated the fluid contents of the gland capsule and gave an injection of T.R. Where the aspirating needle had been inserted a sinus formed which healed after a second injection, and after a third there was no trace of enlargement. I think that post-operative healing is without doubt promoted by the giving of one or two injections of T.R. before operation, which should take place about the time when a third injection is due. The patient's resistance is higher and the general health is better, hence healing is quicker and operation need be less extensive. In *isolated* suppurating glands a small incision, varying in size according to the depth of the gland, with gentle curetting, is all that is required. After two days' packing with gauze the incision may be sutured if necessary without bad effect. If caseating glands are studded around the softened one it is better to excise the whole affected mass. If the glands are calcified excision is to my mind the only course. One cannot expect T.R. to cause absorption of cretaceous material and one ought to get rid of a source of danger to the patient. If the glands have broken down and infiltration of the skin, rupture of the abscess, formation of sinus, and infection of the focus by other organisms taken place I have found that simple T.R. treatment does not suffice in many cases. Either thorough "scraping" or excision of the affected parts should be carried out or else the suitable vaccine or vaccines besides T.R. should be given. One or two injections of streptococcus or staphylococcus or of both should be given. With T.R. alone such cases often improve only to a limited extent and then show no further improvement in spite of variation in the dose or time interval of injection. Of course, the usual precautions which accompany ordinary surgical treatment should be carried out—e.g., removal of bad teeth, enlarged tonsils or adenoids, or other source of infection. Fixation of the part will promote healing of this as of other tuberculous affections. To my mind foul discharging sinuses and hideous scarred necks resulting from advanced tuberculous disease should become unknown. The disease should never be allowed to reach that stage.

Tuberculous joint affections.—Here, again, the prospect is a hopeful one. But ultimate complete success in restoring full healthy function will be obtained only by making a correct diagnosis in early stages and adding T.R. injections to those well proved and approved lines of treatment usually carried out. All the same, one of my joint cases, tuberculous arthritis of the knee, has been completely cured by the employment of T.R. alone. Since the injections were begun the patient has had no splinting or any special local treatment and no other internal remedy has been given. At the commencement of the T.R. treatment he had a sinus, very recently formed, over the internal condyle which was much enlarged. There were thickening of the synovial membrane, effusion into the joint cavity, pain, and much limitation of movement. The joint is now practically normal to appearance and movement has increased by about 45°. The patient has no pain and can run about freely with only the slightest limp. All the same, I recommend most strongly that all treatment which will favourably influence the course of the disease should be employed. One cannot afford conscientiously to run risks with such patients. To my mind, however, a new element has arisen in the treatment. Previously, when a patient was (to even a slight extent) the subject of night-starting, shrieked with pain at any attempt made to move the joint, and when effusion into the joint and thickening of the synovial membrane were present, one gave, to say the least of it, a very guarded prognosis as to the future of that joint. It *might* disintegrate completely and the most favourable outcome was that the disease would subside, but a stiff joint, in more or less good position, was practically certain. Operation cures the disease to be sure in most cases, but in too many it leaves much to be desired with regard to function. In the lower extremity it is practically essential to procure firm ankylosis. I feel certain that the outlook will be far more cheerful when the early use of T.R. is made. I have mentioned one case of arthritis of the knee. I have under treatment a case of tuberculous synovitis of the knee following displacement of the inner semilunar cartilage. Microscopic examination confirmed the diagnosis of tuberculous disease. The knee measured two inches more in circumference than the sound one. Movement was limited to about 30°. In such a case in the event of healing under ordinary treatment one would have expected dense adhesions, but the patient is obtaining freer movement as the joint is rapidly regaining its normal size. The condition was becoming steadily worse before T.R. was given. A third case of hip-joint disease showed the symptoms which I have already indicated (night-starting, pain on handling, and especially on attempted passive movement, &c.). Here I have the advantage of having had my observations confirmed by one of yourselves, who gave a guarded prognosis except that he was quite certain that even the most favourable outcome would be a stiff joint with shortening. With this opinion I was practically agreed. I have no doubt that he will be pleased to hear that the little patient can wriggle about in bed like an eel, can sit almost bolt upright without any sign of discomfort whatever, and allows one to handle the joint without demur. I venture, therefore, to think that such joints should not be absolutely immobilised for the long period which has hitherto been customary. By so fostering adhesions we may prevent what would otherwise be a perfect functional result. If not contra-indicated by the general progress of the case and the tendencies of the patient I suggest that about from two to four weeks after all tenderness on palpation of the joint has disappeared gentle passive movements be attempted every few days and that the patient be allowed well-governed freedom to move the joint if inclined. If any sign of deterioration occurs renew the stringent precautions for another month. Thus I believe that the course of treatment will be shortened by about half of what has hitherto obtained. It is interesting that in a case of resection of the shoulder for tuberculous disease 18 months previously, where the cervical glands in the posterior triangle had recently become enlarged to the size of a hazel nut, the patient stated spontaneously, after a couple of injections of T.R., that movement at the shoulder had become much freer. The glands (one suppurating, aspirated) became impalpable after the third injection. She had a very bad tuberculous family history.

---

[1] A paper read before the Edinburgh Medico-Chirurgical Society on March 7th, 1906.

There is often difficulty in determining whether a deep joint, such as the hip, is really tuberculous. One can come to a decision by giving a big dose of T.R. in order to provoke the local reaction which will occur if the focus be tuberculous. This is very undesirable because one may thus lower the resistance (or, in the language of the opsonist, produce such a decided negative phase) so that the process, instead of being a very chronic one, may light up and prove very difficult to master. It is much better, although not quite so trustworthy, where it is possible to examine the blood only, to ascertain the opsonic index to tubercle bacilli. According to Wright and many others this is of much clinical value. If it be low or unduly high one should at least be very suspicious of tubercle.

A young woman consulted me about her wrist which was giving her much pain and preventing especially her piano playing. There was slight thickening of the proximal end of the fourth right metacarpal bone. This disappeared after fixation of the wrist in plaster-of-Paris for some weeks, but the pain persisted and became worse as time went on and there was a suspicion of recurrence of the thickening of the bone. X rays gave no help. The opsonic index to tubercle bacilli was 0·75, so I began T.R. injections with the result that the trouble rapidly disappeared.

A very different picture from the point of view of rapid results, is presented usually by cases where abscess formation with subsequent development of sinuses and compound infection has occurred. In none have I obtained satisfactory results with T.R. alone unless after operation, and in the majority, although great improvement has occurred, yet it has been slow and subject to occasional retrogression. Here, however, I have not many cases to judge from. One case already recorded was a boy from the poorhouse, with elbow, wrist, metacarpal, and ankle much disintegrated—to say nothing of far advanced disease in his cervical glands. The rapidity with which his lesions healed was very striking. The case of a little girl, in very poor general condition, who came to hospital with a profusely discharging sinus in front of her left hip-joint, is probably the next best in result. The head of the femur was far gone and there was a rather large cavity, filled with pus and lined with very unhealthy granulations, in front of the joint. The bone and cavity were thoroughly scraped. She healed slowly with T.R. but made rapid strides when staphylococcus vaccine was given as well. There remains now only a very small superficial ulcer. In a man, aged 45 years, a very advanced case of hip-joint disease, the result has been unsatisfactory. He was, however, in bad general condition, suffered from incipient waxy disease which caused troublesome diarrhœa, and he persisted in taking unsuitable food. To give him a chance of life I undertook treatment. The head and neck of the femur were rotten and there was besides necrosis of the innominate bone. Numerous foul cavities radiated in various directions from the diseased bone. Several operations were performed. He would not listen to proposals of amputation. After T.R. was given he improved only to a limited extent and then lost ground in spite of variation in dose and time intervals. His opsonic index averaged from 0·75 to 0·8. He improved much more when mixed vaccines of staphylococcus and streptococcus (which organisms were found in the discharge) were used. In fact, only then did any satisfactory healing occur. A large granulating area which had formed in the line of an extensive posterior incision healed with the exception of four sinuses. This area had remained unaltered for weeks. The patient has tired of hospital and gone home and one cannot say that he is better.

I think you will agree after hearing details of these cases at varying stages that it is now even more desirable to prevent, as I believe one can prevent, the very miserable local and general condition of advanced and progressive cases and the disablement and too frequent deformity of cases where cure has been effected. This can be done only by accurate diagnosis and by prompt and rigorous treatment in the early stages. I have no doubt that the very much brighter outlook in these cases will soon be appreciated by those who add T.R. injections to their other treatment.

Tuberculous peritonitis.—In this class I have only one case to record. A hospital nurse, with a very bad family history, developed what turned out to be severe tuberculous disease of the ovaries and tubes, with accompanying peritonitis in the lower part of the abdomen. She had previously a sharp attack of pleurisy with effusion. There were complications, non-tuberculous, which hastened operation. Her right tube and ovary were removed and owing to the conditions it was necessary to leave a tampon in the pelvis, the ends being brought out at the lower part of the abdominal wound. The patient was very ill for many months after the operation and was making a very tardy convalescence, if convalescence it could be called, until injections of T.R. were begun. There was then a most decided change in a week or two. She gained appetite, flesh, and strength. The abdominal wound, which had become a large scooped-out, unhealthy, granulating area, healed until only a small sinus was left. This led into a cavity in the pelvis, which was then drained per vaginam. There is still a very tiny suprapubic sinus. She is now in comparatively robust health and capable of taking a fair amount of walking exercise. Six months ago everyone in connexion with the case thought that the prognosis was well nigh hopeless.

Psoas abscess.—Either aspiration or incision is necessary at some part of the treatment of these cases. Personally, I prefer incision so as to be able thoroughly to evacuate caseous material and pieces of diseased bone, either movable or fixed. I believe that energetic scraping of the abscess wall will be obviated by the use of T.R. I have, however, not had an uncomplicated case of tuberculous psoas abscess to deal with since I have become convinced of the efficacy of T.R. I have to report two cases where multiple infection occurred. One was an anæmic, sallow-looking youth who informed us at the hospital that during the previous week his trousers had rubbed through the skin over a very large swelling in the left groin and upper part of the thigh. A great quantity of pus had escaped. There was a hole in the skin of about one inch in diameter through which masses of caseous material and thin flaky pus were still escaping. The unhealthy edges of the hole were excised by an elliptical incision and the cavity below Poupart's ligament was scraped out. Through an incision above the iliac crest the upper part of the abscess was opened. Several pieces of loose bone were removed and the cavity was scraped in a perfunctory way compared with my usual practice. Both wounds were sutured. All the stitches gave way and for a couple of weeks free discharge occurred. Ten days after his operation T.R. injections were begun. Later he got mixed staphylococcus and streptococcus besides. The granulating wounds kept very healthy and healed rapidly, discharge from the depth soon ceasing. His general appearance and health are vastly improved. The other, a weakly emaciated girl aged 17 years, came to hospital with a sinus in the groin, from which fairly profuse discharge had escaped for several weeks. Otherwise the case was similar to the one already given. T.R. injections had a beneficial effect but far greater improvement resulted when streptococcus and staphylococcus vaccines were used in addition. The wounds have practically healed. Infected psoas abscess is a condition of evil repute, but these cases show that one need not be so hopeless nowadays about the prognosis. Judging from my own limited experience I should have given a bad prognosis in both cases with ordinary treatment.

Tuberculous disease of upper air passages.—A case of rhinitis, with typical tuberculous ulceration of mucous membrane and caries of turbinates and bones of the bridge of the nose, with secondary suppurative infection of the absorbent glands, had been treated over several years by all sorts of local manœuvres with only temporary benefit. The patient came to me again about the middle of January saying that she thought that another operation must be necessary and was afraid that the disease was going to break through the skin at the bridge of the nose. One injection of T.R., supposed to be [illegible]th of a milligramme, produced considerable reaction, lasting for a week. A second smaller dose with staphylococcus added was given after 18 days and repeated at intervals of 14 days. The patient is now almost cured.

Tuberculous teno-synovitis.—A young patient with a bad family history was operated on by me for tuberculous synovitis of the common flexor sheath of her right hand. This was followed by perfect healing, but 18 months later the flexor sheath at the base of the middle finger became similarly affected. One injection produced markedly beneficial effect, in spite of the fact that the movements of the finger were controlled only voluntarily—i.e., no splinting was applied. She was cured after three injections.

Genito-urinary tuberculosis.—As I have taken up too much time already, I do not wish to say much about this except that I have not obtained the constant and progressive good effect from T.R. alone recorded by other observers. In fact, had I begun by trying T.R. on this class I should not have been here to-night, as I should have had so little to record. I am convinced that it is advantageous at an early stage to obtain information as to the nature of the complicating organisms, for in such cases complication takes place early. Then make and use the suitable vaccine. In uncomplicated cases or where purely tuberculous deposits are left behind—e.g., in the prostate or the vesical end of the vas deferens after removal of the testicle—T.R. causes more rapid absorption of such deposits than [illegible]

The use of other vaccines.—Of the effects of other vaccines on their specific diseases I do not intend to say much. I have not so much experience of their use and the results have not been so uniformly striking in cases where the infection was uncomplicated.

The usefulness of other vaccines in conjunction with T.R. in mixed infection of tuberculous foci has been already and probably sufficiently indicated. The same degree of usefulness may evolve in other conditions. It is well known, e.g., that once a gumma has "broken" through the overlying skin or mucous membrane it is frequently infinitely more difficult to bring about cure with ordinary medication than it would have been before ulceration occurred. It is a case of mixed infection again. An example of the good effect of staphylococcus and streptococcus vaccines occurred lately. The patient's back was the seat of several ulcerated syphilitic lesions. Two large areas were covered with rupial crusts and over the erector spinæ opposite the twelfth rib on the right side was a scooped-out ulcer, dirty, sloughy, discharging freely, and smelling badly. It measured two and a half inches across and one inch in depth. All sorts of treatment had been given to these parts by numerous skin specialists in different parts of the country but during the past year they had become rather worse than better. Injections of staphylococcus and streptococcus produced an immediate improvement. The affected areas became cleaner, the granulations more vascular and firmer, and the surrounding parts much healthier and more natural looking. I do not think that healing will occur without operation. Whereas I had scruples about operating from fear of making matters worse I now have none.

Staphylococcus and streptococcus vaccines are of use in another class of diseases, ulcerated cancers. Prompted by Mr G. L. Cheatle's suggestion I have given these vaccines in three cases of extensive operation in the mouth with the idea of preventing septic pneumonia. In one patient, aged 65 years, the extent of the epithelioma required removal of the whole of the horizontal ramus of the lower jaw on one side and of the adjacent part of the floor of the mouth and cheek besides the glands of the anterior triangle. The patient was a weakly, anæmic individual, of a type prone to succumb to pneumonia. In the other cases, one, a case of sarcoma in a patient aged 45 years, and another, a case of epithelioma in a patient aged 63 years, involved, curiously enough, in both patients the removal of the back part of the upper part of the jaw (behind the first molar tooth), the tonsil and adjacent parts of the pharyngeal wall, palate, and tongue, and all the tissues between these and the ascending ramus of the upper jaw. In these cases I consider that septic pneumonia was peculiarly liable to occur. In none of the cases was there ever the faintest suspicion of lung trouble. It would be a great matter if such treatment obviated the necessity of tracheotomy. The injections were given from five to seven days before the operation. The first patient had previously two other injections at weekly intervals. What impressed me was the shrinking and cleaning of the affected areas, especially in the first case. This patient expressed the opinion that operation would be unnecessary if the improvement continued. His mouth was foul from the presence of many carious teeth. The sockets left after extraction previously to operation healed more cleanly and quickly than usual. In this cleansing effect, then, we have another reason for the use of these vaccines before operation in such cases. There are less sloughing and less discharge during the after-treatment and therefore less trouble in keeping the parts sweet and, most important, less danger to the patient. Apparently this beneficial effect begins to diminish after from 10 to 14 days. Injections repeated after the operation will prevent this probably, as evidenced by one of the cases. I intend to widen the sphere of usefulness and make similar injections before such operations as for cleft palate, so as to increase the probability of primary union. Other possibilities crowd into one's mind—e.g., for the prevention of peritonitis as the result of operation for closure of fæcal fistula (here bacillus coli might be given as well), or previously to operations on diabetics or "albuminurics" who are so prone to the onslaughts of septic organisms. In cases of severe accident wounds, although by early thorough mechanical cleansing and clipping away of lacerated structures one procures usually perfect healing, it may be possible to improve statistics further by giving before the operation vaccines of the organisms of suppuration. Where such thorough cleansing has been done I find that when suppuration does occur it occurs at about the end of from seven to ten days and is usually mild in character, so that the positive phase following the injection of the necessary vaccines will have developed several days earlier than this and may prevent such suppuration. The preliminary negative phase might, however, foster the earlier development of the infecting organisms, so before passing any opinion one requires to compare many cases observed by trustworthy men.

In the pure streptococcus or staphylococcus infections one does not require to, one had better not, use vaccines in the early stages. But for the bursting of an abscess or the use of the knife all such cases should, theoretically, according to this resistance theory of Wright, prove fatal, for is there not a continual supply of poison absorbed into the system and should there not, therefore, be a continuous increase in the negative phase? Why should erysipelas become arrested? Why should there be a crisis in pneumonia according to these ideas? I shall not attempt to answer but merely say that theories do not fit all phenomena where living tissues are concerned. Even though such abscesses are not relieved they sometimes dry up and this is more likely to happen the nearer they are to the surface of the body. Certainly the small circumscribed furuncular abscess frequently does. Evidently there is a victory for the tissues and fluids concerned. But yet there is not sufficient resistance provoked, for how often do we see crop after crop of such boils coming out, frequently over a period of months. Here there is a clear indication for the raising of resistance by injection into the general circulation of the specific vaccine, and it has been done repeatedly with success. In *chronic* septicæmia or pyæmia, again, cure will probably be obtained by giving a fillip to the resisting powers by the injection of the suitable vaccine.

One can only indicate probable usefulness for gonococcus vaccine in *chronic* gonorrhœal infections, such as gleet, prostatitis, epididymitis, endometritis, salpingitis, arthritis, and so on.

In a case of pyelitis, where internal remedies, prolonged drainage with daily flushing of the renal pelvis, and plastic operation on the deformed pelvis had failed, I tried vaccine treatment. The vaccine was made by Professor A. E. Wright from the culture obtained from the patient's urine. It was a pure one of bacillus coli. The case was evidently proceeding rapidly to cure, when an attack of influenza occurred and no efforts would induce the number of bacteria in his urine to decrease below from 1,000,000 to 2,000,000 per cubic centimetre. All the same, the average number was at one time about 30,000,000. The progress of this case has been checked by the patient's opsonic index to bacilli coli.

Before proceeding further I should like to say that I would fain avoid technical details in connexion with our subject, my own inclinations being strengthened by a hint from your secretary, but one cannot altogether disregard them. I do not wish to refer to the opsonic index problem further than to discuss the question whether such an estimation is necessary for carrying the great majority of cases to a successful issue. I assert that it is not. If my assertion is wrong it means that many cases deserving of the treatment will have to do without it on account of the expense and labour involved in the calculations. An ordinary practitioner cannot possibly afford the time necessary. Even if he could, unless he has passed through very special training his observations will be of no value. The average patient cannot afford to pay for the services of the skilled bacteriologist as well as those of his own medical man. One must bear in mind that a great bulk of patients of the non-pauperisable working and middle classes are outside the benefits of what may obtain in hospitals. As the usefulness of the treatment is appreciated and its application extends even hospital authorities may grudge to pay for the amount of skilled labour involved if clinical symptoms are not sufficient to guide one during the course of treatment. I assert that accurate clinical observation is quite sufficient, but would repeat that thorough experimental investigation of the effects of any specific vaccine must precede its use clinically in this way in order more easily to arrive at the proper approximate doses and time intervals of giving these. The opsonic index is necessary for the investigator, but not for the clinician in the majority of cases. My cases prove the point very satisfactorily and I think that nothing more need be said by me. One cannot do without the services of the bacteriologist, however. He must find out for us what the organism is which is causing the disease and prepare the corresponding vaccine.

It will be best to consider now what are the proper dosage and time intervals at which the doses should be given. As stated, these must first be ascertained approximately by the bacteriologist. I do not think that one can be dogmatic about dosage. From my experience in this line I should say that one of the important things is *to get rid of the inclination to increase doses* so as to produce better results. Not very long ago Professor Wright was kind enough to send me a list of the doses of a few of the vaccines which he had been giving. They were as follows: Staphylococcus, from 500,000,000 to 1,000,000,000; streptococcus, from 100,000,000 to 250,000,000; gonococcus, from 50,000,000 to 250,000,000; bacillus coli, from 100,000,000 to 1,000,000,000; and tuberculin R., from $\frac{1}{1000}$th to $\frac{1}{400}$th of a milligramme. I should say that one should give even less than these. For example, I have been getting very marked results from the use of about one-sixth of this amount of staphylococcus vaccine at a time. As Professor Wright says, it seems well also to prolong the interval and to lessen the dose of vaccine in the later stages of treatment.

The dose of T.R. which I have been giving usually is $\frac{1}{500}$th of a milligramme for either adults or children beyond the age of from three to five years. Children seem to be able to stand relatively more than adults, although I cannot say that the good results have been more striking or rapid. The doses have been repeated at intervals of usually ten days, lengthened to about 14 days if so indicated by the clinical symptoms. After two or three months repeat only every three or four weeks. After the performance of any extensive operation or one in which vigorous scraping has been done, it is better to omit the dose until from 10 to 14 days have elapsed, because a negative phase is produced by such operations. For the same reason I do not give a dose for a few days after the patient has arrived in hospital, especially if there is much discomfort about the affected part or rise of temperature. It would appear to most to be quite a simple matter to dilute the solution of tuberculin to easily manipulable strength, but this is not an easy thing to do accurately and aseptically. I prefer to get it done by the trained bacteriologist. I have reason to say that accuracy in this matter is important. As I have indicated, doses of from 50,000,000 to 150,000,000 of staphylococci seem to me to be quite sufficient. I have given them at intervals of from five to eight days before operation and at similar intervals in ordinary curative treatment. From 50,000,000 to 100,000,000 of streptococci have been given at similar intervals in similar circumstances. Bacillus coli gives, I should say, best results in doses of from about 50,000,000 to 150,000,000. In my experience doses above that are likely to produce severe general reaction. In giving mixed vaccines it is apparently immaterial, so far as T.R., staphylococcus, and streptococcus are concerned, whether they are given together or alone. Apparently each works quite independently of the other. This fact has also been proved experimentally. The nearer to the surface of the body these vaccines are injected the more likely are they to produce an intense reaction at the point of injection. This refers especially to staphylococcus and streptococcus vaccines. Therefore it is best to inject into the belly of a fleshy muscle and to make the patient move the part so as to dissipate the dose. It is well that the patient should not indulge in exercise for some hours after the injection.

Now comes the question, what are the clinical symptoms by which one can be guided reliably? One should give a dose which will just fall short of producing a definite local or general reaction. If larger doses are given too great a drop in resistance may be caused and harm result by providing freer scope for development of organisms previously more or less inert and under control of the patient's defensive system. Witness the results in the days when tuberculin was first used! If too large a dose be given the patient may have discomfort or actual pain, swelling, and other increased inflammatory signs in the part affected. General signs which I have noted are headache, loss of appetite, malaise, nausea, even vomiting, rise of temperature, aching bones or joints, and in the cases of streptococcus and bacillus coli severe rigors have occurred.

If the vaccine be doing good the great majority of my patients have experienced improvement in the part affected and have shown and expressed marked improvement in general health, their appetite and sleep have improved, they became brighter, and they put on flesh. For a day or two following the earlier injections there may be such slight [illegible] or discomfort to the extent of

of from seven to ten days and is usually mild in character, so that the positive phase following the injection of the necessary vaccines will have developed several days earlier than this and may prevent such suppuration. The preliminary negative phase might, however, foster the earlier development of the infecting organisms, so before passing any opinion one requires to compare many cases observed by trustworthy men.

In the pure streptococcus or staphylococcus infections one does not require to, one had better not, use vaccines in the early stages. But for the bursting of an abscess or the use of the knife all such cases should, theoretically, according to this resistance theory of Wright, prove fatal, for is there not a continual supply of poison absorbed into the system and should there not, therefore, be a continuous increase in the negative phase? Why should erysipelas become arrested? Why should there be a crisis in pneumonia according to these ideas? I shall not attempt to answer but merely say that theories do not fit all phenomena where living tissues are concerned. Even though such abscesses are not relieved they sometimes dry up and this is more likely to happen the nearer they are to the surface of the body. Certainly the small circumscribed furuncular abscess frequently does. Evidently there is a victory for the tissues and fluids concerned. But yet there is not sufficient resistance provoked, for how often do we see crop after crop of such boils coming out, frequently over a period of months. Here there is a clear indication for the raising of resistance by injection into the general circulation of the specific vaccine, and it has been done repeatedly with success. In *chronic* septicæmia or pyæmia, again, cure will probably be obtained by giving a fillip to the resisting powers by the injection of the suitable vaccine.

The nearer to the surface of the body these vaccines are injected the more likely are they to produce an intense reaction at the point of injection. This refers especially to staphylococcus and streptococcus vaccines. Therefore it is best to inject into the belly of a fleshy muscle and to make the patient move the part so as to dissipate the dose. It is well that the patient should not indulge in exercise for some hours after the injection.

Now comes the question, what are the clinical symptoms by which one can be guided reliably? One should give a dose which will just fall short of producing a definite local or general reaction. If larger doses are given too great a drop in resistance may be caused and harm result by providing freer scope for development of organisms previously more or less inert and under control of the patient's defensive system. Witness the results in the days when tuberculin was first used! If too large a dose be given the patient may have discomfort or actual pain, swelling, and other increased inflammatory signs in the part affected. General signs which I have noted are headache, loss of appetite, malaise, nausea, even vomiting, rise of temperature, aching bones or joints, and in the cases of streptococcus and bacillus coli severe rigors have occurred.

If the vaccine be doing good the great majority of my patients have experienced improvement in the part affected and have shown and expressed marked improvement in general health, their appetite and sleep have improved, they became brighter, and they put on flesh. For a day or two following the earlier injections there may be such slight [illegible] increase in discharge or discomfort to the extent of

successful, which would easily be explained by the fact that streptococci are from various sources of different strains.

The following is a very brief account of the three cases of malignant endocarditis in which this method was adopted.

CASE 1.—The patient, a young woman, aged 26 years, was admitted into Mill-road Infirmary three days after delivery of a stillborn child. The labour was a difficult one and instruments were necessary to deliver the child. On admission she was in a state of acute puerperal septicæmia. The temperature was 103° F. and the pulse was 140 and very feeble. She was partially delirious. The genitalia and uterus were carefully examined and a swab was taken from the interior of the uterus which showed streptococcus on agar tubes. She was immediately given 20 cubic centimetres of serum as above indicated in the rectum night and morning. On admission the heart sounds were pure but on the third day after admission a soft blowing systolic murmur was heard over the apex and confined to the mitral area. On the next day she was seized with violent rigors, sweatings, and great restlessness, her temperature being 106° and the pulse 140. After each injection of serum there was a drop in the temperature of about two degrees and she expressed herself as feeling easier. The rigors ceased and the sweating was less. The murmur, however, became louder and harsher and in spite of all treatment she died six days after admission. In all she had 200 cubic centimetres of serum.

At the necropsy the uterus was found to be enlarged and flabby and the endometrium was acutely inflamed and covered with a greyish slough. There was no retention of placenta or any débris. The heart was enlarged and weighed 13 ounces. The mitral valve was in a state of acute infective endocarditis and streptococci were readily stained from it. There was no other lesion to be found and the case was evidently a very acute infective septicæmia which would have required an enormous amount of serum to combat successfully.

CASE 2.—This was an example of the cardiac or malarial type in which the heart has been damaged by previous disease. The patient was a woman, aged 26 years, who was admitted to hospital in a serious condition. She had suffered from heart trouble for ten years, the result of rheumatic fever, but had been able to work up to a week before admission. She was at that time seized with great pain in the cardiac region, shivering fits, and general malaise. On admission her temperature was 104° F., the pulse being 120, small, and irregular. On examination the heart was found to be much enlarged, with loud mitral presystolic and systolic murmurs. The murmurs were particularly harsh and rasping, with great cardiac irregularity. She had a large tender spleen, numerous petechiæ over the arms and chest, profuse sweating, and violent rigors at intervals, together making a typical clinical picture of infective endocarditis. Her case seemed desperate. She was given 20 cubic centimetres of serum night and morning and after the second dose she felt relief. Her temperature dropped at once, the pulse became slower and steadier, and she felt easier. After each injection she felt better, the rigors rapidly disappeared, the sweating became less, and she was able to converse and to explain her symptoms. The injections were continued for 20 days; in all a total amount of 560 cubic centimetres of serum was given and her condition was immensely different. The temperature became normal, the pulse 100 and regular, and the murmurs much softer, and this condition continued for five weeks, during which time she was comparatively comfortable and free from dyspnœa and pain. The damaged heart, however, remained and she died somewhat suddenly from embolism six weeks after the temperature had become and remained normal. Unfortunately no necropsy was obtained.

CASE 3.—This patient, a woman, aged 23 years, was another instance of the cardiac or malarial type where the heart had been previously seriously damaged by an attack of rheumatic fever. On admission she was suffering from a typical attack of acute infective endocarditis with a temperature of 103° F. and persistent and recurring rigors. The aortic valve was seriously damaged, with all the symptoms of stenosis and regurgitation. The murmurs were harsh and loud and there was considerable dyspnœa, the patient having to be propped up in bed. She was given 20 cubic centimetres of serum morning and evening and almost immediately she got relief. The rigors ceased entirely after three injections, the sweating was less, and she felt less headache and oppression. The temperature gradually dropped and reached the normal in ten days. Altogether 580 cubic centimetres of serum were used, with no pain or discomfort and no sign of erythema or urticaria. Her condition rapidly improved until in three weeks she was entirely free from symptoms or distress. She was discharged to the convalescent home in a good condition.

Remarks.—From a prolonged use of polyvalent antistreptococcic serum per rectum I am satisfied of its greater efficacy and personal comfort than by injecting it under the skin. This antistreptococcic serum, however, is only an antimicrobic serum and has no antitoxic action. What the result of injecting antitoxic sera by the rectum would be I do not know as I have had no experience. There can be no possible doubt, however, as to the great value of antistreptococcic serum in pure streptococcal infections and the preparation of a polyvalent serum is a great step in the treatment of these acute and often fatal diseases.

Liverpool.

THE TRAINING OF NERVE CENTRES IN CHILDREN.[1]

BY G. ERIC CAMPBELL PRITCHARD, M.A.,
M.D. OXON., M.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE ST. MARYLEBONE DISPENSARY; LATE
CLINICAL ASSISTANT, VICTORIA HOSPITAL FOR CHILDREN, ETC.

IN presenting to the society my views on the subje which forms the title of this paper I make no claim originality. I am simply rehabilitating an old friend in ne vestments and attempting to express in words certa thoughts and ideas which in some form or other mu have occurred to all of us. Practical psychiatry h recently taught us many a useful lesson concerning th development and training of the defective mind; what I a going to say this evening is concerned with the applicatio of the same fundamental principles to the training an education of those lower nerve centres which control th humbler organic functions and which, not only in mentall defective children, but also in children of superior intelli gence, often suffer from certain initial disabilities.

Though all of us are perfectly well aware that ever organic event that takes place in our bodies is the expressio of a reaction to outside agencies or the response to stimula tion by the environment, in the practical domain of medi cine and in the treatment of symptoms we seldom pause t consider that all these reflex actions represent chemical an physical changes set up in the central nervous system b forces reaching it from outside and that the objectiv manifestations of these changes are only secondary event occurring in the muscles and in other organs. In othe words, we rivet our attention on the instrument which dis plays the function and not on the hand that guides th machine. How many of us, for instance, when we have t treat a case of dyspepsia think of possible disturbances i the nervous centres which control the functions of digestion Do we not rather think of the pathological condition of the gastric mucous membrane or of disabilities of the motor functions of the stomach? The irrational and unscientific classification of diseases into functional and organic varieties has doubtless predisposed to this narrow conception of morbid processes. Every disease must primarily be functional in character. Whether organs do their business well or badly depends almost entirely on the central administration of the nerve cell; *for the special activities of organs, as well as their nutritional and vegetative functions, are inseparably bound up with impulses which emanate from this central authority.*

In the same way that in the treatment of disease our natural inclination is to consider the organ rather than the nerve cell that directs its activities, so in the physical education or training of the ordinary bodily functions we incline to direct our energies to the instruction and improvement of the organ with which we are concerned and momentarily forget that the only portion of the entire reflex arc which has a memory or is capable of instruction is the nerve cell which

---

[1] A paper read before the Chelsea Clinical Society on Feb. 20th, 1906.

food will be deleted from the list to which civilised man is erroneously supposed to be born the heir.

Some children are very much easier to train or to educate in the normal performance of the organic functions than others. Thoroughly degenerate infants lose, or rather, we should say, never acquire, proper control over such ancient, automatic, and stereotyped actions as those exercised by the cardiac and respiratory centres; others of a lesser degree of degeneracy fail to acquire complete and coördinate control over such easily managed functions as those of sucking, deglutition, &c. Personally I always take a *most unfavourable view* not only of those infants who require artificial stimuli to induce natural respiration at the time of birth but also of those who fail in coördination of such primitive muscular acts as those involved in sucking, swallowing, and in the motor functions of the stomach and bowel. How very easily these indications of incompetent nervous control can be overlooked in early infancy is illustrated by the fact that I have *twice* seen infants operated on for tongue-tie who were really examples of inherited nervous degeneracy and who were unable to perform the simple coördinated function of tongue extrusion.

Precocious children, especially those born of intellectual parents, acquire early control over the higher cerebral centres which depend for their activity on the coördination of impulses reaching them through the nerves of special sense. As a rule, too, in such children the lower centres which administer to the organic functions are exceedingly receptive to educational stimuli; but too often they develop at a rate which is incompatible with permanency and stability and soon show signs of premature decay. The nervous *instability of these precocious children* who have anticipated the natural progress of evolution and lived before their time cannot always be easily distinguished from that other form of nervous disability which is truly degenerative and indicative of a reversion to a more primitive type. Indeed, it is very difficult to say what is degeneration and what is evolution.

That higher sensitiveness of the nervous system to external stimuli, which in so-called neurotic individuals is very often the basis of their genius and intellectual superiority, carries with it at the same time certain disadvantages when viewed from the standpoint of the lower centres. For these centres, owing to their inherent excitability and sensitiveness, are not only liable to explode with dynamic energy in the face of *subminimal stimulation*, but they also *tend to* discharge neighbouring and associated centres by permitting of an overflow of their excessive energy. Thus in neurotic infants, provided with hair-trigger centres of this kind, the insignificant stimulus of an erupting incisor tooth may provoke not only local manifestation but even a general overflow of incoördinated and explosive discharges which take the form of *convulsions*. *Involuntary nocturnal enuresis and involuntary masturbation* in infants are examples of the hair-trigger-like action of the lumbar centres. Spasmodic asthma and, indeed, I would venture to suggest bronchitis, are similar explosive neuroses of the respiratory centres, and spasm of the pylorus and larynx affords other instances of a like instability in other cell-groups in the central nervous system.

The sound education of *these* lower centres in neurotic subjects is a matter of great difficulty; two main principles, however, must be borne in mind. Firstly, that all these centres are hypersensitive to external impressions, and that they respond to stimuli which in normal and stable children would be subminimal and incapable of eliciting a discharge, and secondly, that the memory of these centres is highly developed, so that they very easily contract habits, both good and bad. Neurotic children should therefore be protected from every possible form of strong stimulus, whether this stimulus take the form of food, of extreme degrees of cold or heat, of light, of sound, of pain, or of pleasure—otherwise their centres will explode with violent and ill-coördinated energy, and the vicious habit will be perpetuated to the detriment of the harmonious coöperation of the organic processes of the body.

I have referred to the pathological overflow of ill-coördinated and stormy nervous disturbances which pass from one centre to another as the result of supermaximal stimulation, and by way of illustration I would mention the violent jump which a nervous child may make when he hears a loud and sudden noise. I may add that exhaustion of *contiguous centres* is an analogous consequence of longer and more sustained stimulation. Instances of this kind are familiar in the exhaustion of the centres governing the acts of defæcation and micturition, which follows as the result of prolonged labour in women; the spinal centres which control these muscular coördinations are in their anatomical relationship closely associated—and exhaustion in any one of them is followed by exhaustion in the others. Again, the whole arm, or indeed the whole body, may become tremulous and incapacitated for finely coördinated actions if the centre for so small a muscle as the extensor indicis become fatigued by intermittent contraction. There is, however, a physiological corollary which follows from this reciprocal interaction between centres and it is that the energy stored up in one centre can be drawn upon by adjacent centres when the latter become exhausted. This reciprocal support is well shown in the case of the higher cerebral centres, indeed, as Dr. L. H. Gulick[2] says, "the motor brain seems to be a sort of battery furnishing power for intellectual labour." Physical endurance as well as intellectual endurance depends, not only on the degree of development of the special centre concerned but also upon the storage capacity of the whole battery of centres. The fact that the motor brain can act as a sort of storage battery for the display of intellectual labour and that there can be an exchange of energy between more or less closely associated centres emphasises, in a physiological sense, the importance of an adequate development not only of special motor centres but of every available nerve-cell that can take part in any possible muscular coördination.

It has been said, and I believe truly said, that both in animals and in man "the scale of intelligence corresponds to the number of possible muscular coördinations, the more complicated the neuro-muscular apparatus the higher the intelligence." Indeed, whether we think, *feel*, or will, we repeat, as it were, in subjective pantomime the neural and muscular process whereby we obtained our original information. In view therefore of its influence on the development of the intelligence apart from every other consideration the training of the muscles and the various muscular coördinations from earliest infancy onwards is a matter of the utmost importance. *Infants and children should not only be* encouraged to develop their motor centres by the voluntary exercise of their muscles, but they should be systematically taught movements and combinations of movements for which they show no special inclination. Clumsy and ill-coördinated movements are indicative of similar methods of thought and there is no physiological stigma of degeneracy *that more* accurately reflects a debased quality of the central nervous system than want of adjustment in the finer muscular coördinations. Although no amount of training or education will convert a nervous system that is intrinsically inferior into one that is even relatively good, nevertheless a great deal can be done by educational discipline to compensate for initial inferiority and to raise it to a higher standard of functional efficiency.

Without entering into details and special methods of muscular training for infants and children, I would refer to a general principle which applies not only in this case but in the *training of all centres throughout the cerebro-spinal system*, and this principle is that each centre should be developed in its natural order—and by natural order I mean the sequence in our ancestral history in which each has been acquired. Certain muscular coördinations are, in this phylogenetic sense, comparatively old, as, for instance, the coarse movements of the limbs and trunk, so also are the grasping movements of the hands. These latter are well developed at the time of birth, but the independent and finer coördinations of the fingers, in conformity with their more recent acquisition, show no spontaneous tendency to development *until the child is considerably older*. "*Nothing* but disaster," says Dr. Gulick, "can be expected if we attempt to force motor education out of its natural order." The education of any part is best done when that part is ripening and the physiological moment *is determined* in accordance with the antiquity of its acquisition. Anticipation or procrastination are equally fatal. "When," says the same author, "special attention is given to specific exercises demanding skill in distal groups of muscles, before the more proximal have been trained, we often find neuroses supervening." Instances of this kind are demonstrated by infant *prodigies* who have been prematurely trained in special lines of muscular efficiency—as, for instance, in playing the violin or piano. It is therefore thoroughly irrational to teach

Ibid., p. 242.

that is necessary for the education of the higher cerebral centres but I maintain that it deserves far more consideration than it usually receives and that the two are very closely bound up together. At the cost of again repeating myself I would remind you that any sound method of educational discipline of the lower nerve centres in children must take cognisance of the three fundamental principles to which I have already referred—namely, the avoidance of supermaximal stimulation, the prevention of the acquisition of explosive neuroses through the habit of over-action, and the education of each centre in its natural order of development.

South Kensington, S.W.

A CASE OF ASCITES TAPPED SIXTY-NINE TIMES.

BY FREDERICK H. MABERLY, M.R.C.S. ENG., L R.C.P. EDIN., L.S.A. & L.M.

THE patient, a man, aged 52 years, consulted me first in March, 1901. He was then suffering from an enlarged, flabby, and very irregular heart, a liver reaching three inches below the ribs, and on boiling some urine in a test tube the deposited albumin reached about half way up the column of fluid. During the next few months four of our Birmingham consultants saw him with me and all felt that he had only a short time to live. His legs became very œdematous (for this I used acupuncture with very good results) but on March 11th, 1902, I had to relieve the abdomen which had gradually filled; this I did in the ordinary way with the usual trocar and cannula, but finding how exhausted he was after the operation I concluded that the very rapid extraction of heat contained in two gallons of fluid was the cause and determined to adopt another method, so on the next occasion, March 27th, I used a small exploring needle the cannula of which had a diameter of only one-sixteenth of an inch. The drawing off of the fluid this time gave him no inconvenience, but, on the contrary, he was greatly relieved and felt perfectly comfortable on the next day. I tapped him 24 times in 1902, 21 times in 1903, 10 times in 1904, and 14 times in 1905, in all, 69 times, which I think is a record. The *modus operandi* was as follows. First I sterilised my instruments by placing them in a solution of formalin, sponged the skin, and washed my own and the nurse's hands with the same; then I injected hypodermically half a grain of cocaine deeply, allowing seven or eight minutes to elapse, when after emptying the bladder, I punctured through the linea alba, midway between the umbilicus and pubes, then removed the trocar and left the abdomen to drain, which generally took about one and a half hours. The patient's sister, who nursed him most assiduously throughout his illness, attended to the draining, then removed the cannula, and applied a small piece of sterilised wool, with adhesive plaster to the puncture and the operation was over. A belt was worn to support the abdominal walls. After adopting this plan the patient never suffered the slightest pain during the operation, nor had he any depression afterwards but was always much better and more cheerful on the next day, although the usual quantity of fluid removed was about two gallons.

I report this case thinking that it may be a help to my professional brethren in treating similar cases. The patient died from coma on March 14th, 1906, but until shortly before his end he had a very comfortable existence during the four years during which the treatment undoubtedly prolonged his life.

Birmingham.

A NEW METHOD OF OPERATING IN PANNUS.

BY WILLIAM PRIMROSE, M.B., C.M. GLASG., M.R.C.S. ENG.

FOR some time I have been employing a new method of operating in cases of pannus which is so simple and satisfactory that I think it deserves to be better known. The operation consists in causing an extravasation of blood into the subconjunctival tissue around the cornea. This by its mechanical pressure and by acting as an irritant foreign body setting up a localised inflammation, causes the obliteration of the vessels which vascularise the cornea. The only instrument required is a small sharp-pointed knife—a Beer's cataract knife does very well for the purpose. The point of the knife is passed through the conjunctiva at a distance of two or three millimetres from the cornea and made to puncture one of the larger blood-vessels. The knife is then withdrawn. The conjunctival wound should be as small as possible and made obliquely by holding the knife at an acute angle with that part of the surface of the eyeball which is being operated upon. In this way there is no external hæmorrhage; but bleeding takes place into the subconjunctival tissues and is arrested automatically by the pressure of the extravasated blood upon the vessel walls. In like manner many of the smaller vessels in the vicinity are mechanically closed. This mechanical action is increased by the formation of a coagulum, the fibrinous part of which shrinks and makes the whole mass smaller. Extravasated blood acts as an irritant, probably chemical as well as mechanical, so a non-infective inflammation is set up which results in the absorption of the blood clot. This process acts as a counter irritation to the inflammation of the corneal tissues and so tends to remove the seat of inflammation and the supply of blood from the diseased cornea to the clot, where the effects of the inflammation are comparatively trivial. By the time the blood clot has disappeared the blood-vessels in the cornea affected by the operation have shrivelled up and the cornea has regained much of its transparency. The whole pannus may be treated in this way at one time or the operation may be repeated from time to time, only a part of the pannus being treated each time. The latter is always advisable when the pannus is marked, as the inflammatory reaction is sometimes very severe and accompanied by a good deal of pain. Although the structures in the anterior part of the eyeball are all more or less affected by the inflammation this is easily controlled and subsides in a few days with the application of suitable remedies.

A patient, 35 years of age, recovering from trachoma had pannus equally marked in both eyes. He had one eye treated by the new method and the other by peritomy. Although the process of cure was attended by much greater suffering in the eye treated by the new method, the result of the operation was much more satisfactory than was that in the eye on which peritomy was performed.

Glasgow.

A CASE OF RUPTURE OF THE SAC IN ECTOPIC GESTATION.

BY JOHN H. TONKING, M.B. LOND.

MY excuse for publishing this case is the paucity of symptoms on which reliance had to be placed in order to arrive at a diagnosis.

The patient was a woman, 39 years of age, who had had 12 pregnancies, in the ninth of which she was delivered of twins. Her twelfth child was born on July 2nd, 1905, and was not nursed by the patient. Menstruation recommenced early in October and continued regular until early in January, 1906, when it stopped, but came on early in February. Instead, however, of ceasing as usual at the end of a few days it continued intermittently and not profusely until March 10th, when the patient was seized with violent abdominal pain causing vomiting. She was seen by a colleague who found her with no rise of temperature but with a pulse-rate of 120. Opium pills were given and on March 11th my colleague reported that she had less pain but that her pulse was still quick. The place of greatest pain was over the region of the gall-bladder. On March 12th at 6 P.M. I was requested to see her and found her in an attack of great pain, with no rise of temperature and a pulse-rate varying from 120 to 140. She was very anæmic. A diagnosis of internal hæmorrhage was considered probable and the patient was removed to the Women's Hospital at Redruth. After a consultation with Dr. Frank Hichens, ether was administered by Dr. William Blackwood, my partner, and I performed laparotomy at 10 P.M. the same night. As the patient was collapsed during the operation two and a half pints of saline solution were injected into the median basilic

growth is no doubt a phlebolith, or at any rate had a similar origin to such concretions. It has a fibrous structure, calcified in places. There are no nuclei visible anywhere."

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Observations on Endemic Goitre in the Chitral and Gilgit Valleys.

A MEETING of this society was held on April 10th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

The SECRETARY, in the absence of the author, Captain R. McCARRISON, I.M.S., read a paper dealing with the results of three years' observation in Northern India in two districts, Chitral and Gilgit. The Chitral country was mountainous. The villages were all situated on alluvial fans at the mouths of nullahs. The rocks were everywhere metamorphic, gneiss and slate predominating. But the most goitrous villages were invariably associated with limestone outcrops. The climate was temperate and the rainfall was small. The people were poor; their food was entirely vegetable, consisting of the poorest grains. Fresh meat was quite beyond their means, while salt was a luxury unknown to any but the richest families. The water-supply was in all cases derived from the melting of the snows on the hills above. It ran down the nullahs as a turbulent mountain stream, taking up what matter it might, either in solution or suspension. In the summer months the water was invariably grey from the presence of fine sediment. There were no real glaciers in the district under observation; the water was snow- rather than glacier-water. The villages had no wells and, owing to the slope of the ground and the nature of the soil, water did not and could not stagnate. The analysis of the water-supply showed: 1. That the waters varied largely in composition for the various villages. 2. No single dissolved ingredient appeared to have any influence in the production of the disease. 3. The total solids and the total hardness of the water appeared to have no influence in the production of the disease. Goitre was very common among children of all ages. Children at the breast were not free from the disease. Females appeared to suffer more than males. In one instance observed 18 per cent. of susceptible individuals, natives of non-goitrous areas, developed the disease after a residence of four months in one of the most goitrous villages. In another case, of ten young men from the plains of India, two, or 20 per cent., developed goitre in two and a half months. It was further noticeable that 32 per cent. of male children under one year of age in three of the most goitrous villages taken together suffered from the disease. These might, of course, be congenital but it was reasonable to suppose that some were acquired. Symmetrical goitres, diminished in size, except in old cases, when the subject left the area where the disease was acquired. They again increased in size on return. This rule would appear to apply even when he went to another goitrous district if sufficient time had not elapsed for him to come under the new influences. Experiments were tried on the influence of boiling and filtering waters supposed to be capable of causing the disease. Of ten dogs experimentally tied up in extremely goitrous houses for two months, five being given boiled and five ordinary water, one of those kept on ordinary water developed the disease. In Gilgit and Nagar the geographical, physical, and social conditions were similar to those in Chitral. The water-supply came from a single source and was conveyed to the different villages in open channels. This water was capable of producing 11·8 per cent. of goitre at its source, while at its terminus, after having served indifferently as drinking channel and open sewer for the villages on its banks, it caused the disease to the extent of 45·6 per cent. There was, however, a village served separately by a small spring entirely free from the disease in which no case of goitre due to the drinking of this water could be traced. This fact pointed to the very important conclusion that the other water-supply was the vehicle of the disease in Gilgit. It was noteworthy that the villages highest up on the channel showed the lowest percentage of disease and that this percentage increased proportionately until a maximum was reached at the terminus. This increase, however, did not occur in children under 15 years of age. A considerable outcrop of limestone occurred in the nullah from which Gilgit derived its water-supply. Qualitative analysis of the waters of these different villages showed no variation in their composition. Organic impurities were not readily detected in the water lower down owing to the fact that this water was continually being replaced by a purer supply from above. The chief characteristic of the water near its source was the presence of a large quantity of diatoms, amongst which eucyonema and navicula were most common, together with the absence during the winter months of much matter in suspension. At its terminus, on the other hand, diatoms appeared to be fewer in number, while suspended matter was extremely plentiful. Captain McCarrison next dealt with the case of Nagar. Up to six years ago Nagar was an independent State, cut off by inter-tribal jealousies from practically all communication with goitrous districts. During recent years intercourse with the outer world had become more free. Some five years ago certain individuals suffering from goitre settled in the country, where previously the disease was absolutely unknown to originate. Throughout Nagar goitre is now spreading in a typically epidemic form, its first victims being among children under ten years of age. The water-supply of Nagar, where the disease is spreading, came from a spring. This spring was said to have existed from time immemorial. The chemical composition of its water had presumably not altered. The conditions of life of the people were the same. The only added factor was the introduction of goitre from without. It appeared also evident that it was by means of the spring water that the disease was now spreading, for the 12 children affected were residents of that part of Nagar supplied by the spring. It was further important to notice that the family first to import the disease lived at the head of the spring and that no cases of goitre were observed where water from other sources only was drunk. The following conclusions were drawn:—1. The water-supply of Gilgit was the vehicle of the spread of the disease. 2. This water-supply was able, at its source, in its unassisted state, to produce 11·8 per cent. of goitre. At its terminus, after passing through seven villages and proportionately increasing in its goitre-producing powers on its downward passage, it reached a maximum of 45·6 per cent. 3. There must, therefore, between source and terminus, be added some poisonous element representing this difference of percentages in the disease. 4. The added element was matter in suspension. 5. The matter in suspension might be either (*a*) inorganic substances or (*b*) micro-organisms. 6. The striking case of Nagar could only be explained on the latter (*b*) assumption: that was to say, the introduction from without of a micro-organism into a suitable water-supply, and the consequent spread of goitre in a typically epidemic form. The hypothesis which assigned to micro-organisms the causation of the disease was further supported by the following facts: (1) the large percentage of goitrous children under one year of age in Chitral could be explained in this way without recourse to a conclusion that such cases were congenital; (2) it accounted also for such instances of the disease which could not be traced to a water-supply and admitted of the broader view that water, if it was the chief vehicle of infection, was not the only one; (3) it explained readily the regular increase of the disease from source to terminus of the Gilgit water-supply; and (4) finally, it explained the differences in the charts for the areas of Chitral and Gilgit which seemed to indicate the natural, *if slow, end of an epidemic of goitre.*

Mr. JAMES BERRY referred to the great importance of discovering the cause of this disease, with which were associated other conditions of physical and mental deterioration. There were two methods of studying the subject—first, to investigate the disease in one place, all the surrounding factors being taken into consideration; and, secondly, to visit and to investigate numerous goitrous districts. He had adopted the second method and had visited many goitrous districts in this country and abroad. Captain McCarrison's observation agreed with his own observation that goitre occurred most commonly in mountainous districts, and he showed a map demonstrating the fact that goitre occurred in the mountainous districts of France and also in the hilly parts of England. Another striking point was the connexion between limestone and goitre. He quoted statistics to show

build.—Dr. F. E. Fremantle referred to Selangor in the Straits Settlements where the engineer who first laid the plans in the jungle provided, in spite of opposition and ridicule, for a town which had now in his lifetime attained a population of 70,000. He adduced the case of the "Garden City" and of Bournville, which were conducted on strict business lines.—Dr. J. C. McVail, Dr. A. Newsholme, Dr. W. Butler, and others asked numerous questions on matters of detail, to which Dr. Robertson replied that except in the case of roads over a certain width the owners paid for the making as in this country. He could not explain how urban and rural districts were respectively rated but he knew that the principles of rating were wholly different from what they were here and that the municipalities always kept a portion of their areas open and rural. The authority prescribed the alignment and width of streets, the height of the houses, and their connexion with the sewers, and so on, but all matters of construction, plans, and materials of houses were subject to the regulation of the (sanitary) police. Owners could not be compelled to develop their land and might hold it back until they could obtain by sale the unearned increment in the value of the site, but this was very rarely done.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held at Bath on March 31st, Dr. G. W. Hamilton Cumming (Torquay), the President, being in the chair.—After an inspection of the Royal Mineral Water Hospital an ordinary meeting was held at the Guildhall.—The President remarked that as Bath had been chosen for the first meeting of the society in the provinces, and as the Bath waters were the only true thermal springs in the country, Thermal Methods had been chosen for the discussion. He hoped that cases proved to be unsuitable for treatment at Bath would be mentioned.—Dr. Charles Begg (Bath) laid emphasis on the superiority of a natural thermal water in the treatment of disease as a result of his experience here and elsewhere. Bath was the only natural hot-water spa in Great Britain. When *cold* mineral water was heated gases were given off and solids precipitated and the result approximated more or less closely to pure water. The remedial agent was still uncertain—whether the natural heat, the stimulation of nerve terminals by salines, the action of gases, or the radio-activity. An important point was the season of the year. Bath had been called relaxing in summer, but that was its strong point. They could not relax too much a patient from whom they were trying to eliminate a systemic poison.—Dr. Alexander Morison (London) remarked upon the natural pre-eminence of Bath as an English thermal spring and argued from its ancient reputation that the waters could effect much without the complication of electric baths and other modern addenda to balneological treatment. However wide might be the domain of practice in Bath or elsewhere he considered that the interests both of Bath and its invalid visitors would be best consulted by the special treatment by natural balneological methods of suitable articular and neuritic affections, only.—Mr. T. Pagan Lowe (Bath) said that the thermal methods employed at Bath did not differ materially from those which obtained at other first-class balneological resorts, such as Buxton and Harrogate, and included in addition to every modern thermal water appliance, the Greville, the Dowsing radiant heat, sinusoidal electric baths, and high-frequency appliance. 40 years ago the "season," like other watering-places, was essentially a summer one but now Bath was the only winter health resort in Europe and its "season," which began in October, continued without interruption until the following June. Surgical methods as applicable to chronic joint disease formed an important adjunct to Bath treatment and were practised with considerable success.—Dr. H. Forestier (Aix-les-Bains) mentioned the various "thermal methods" which had been in use for centuries in spas and pointed out that bathing, douching, and hot vapour baths were the chief ones. About 1810 a new thermal method was brought into the practice at Aix-les-Bains, the douche combined with massage, the latter being imported from Egypt at the time of Bonaparte's expedition. This "douche-massage" seemed to be the more effective thermal method as carried out at Aix-les-Bains. Its effect on the metabolism was much greater than the simple douche. The efficacy of "douche-massage" had led to its adoption at other continental spas as well as at the British spas.—Dr. W. Johnson Smyth (Bournemouth) considered that in rheumatic and gouty conditions, and also in some forms of neurasthenia, where rapid chemical changes in the system were desirable, there could be no question as to the beneficial effect of thermal treatment. Some rheumatic conditions associated with, or due to, morbid functional activity on the part of the nervous system were readily amenable to thermal treatment. In neurasthenia thermal treatment was found to be of the greatest use. It was possible that in the early embryological relationship existing between the superficial layers of the skin and the cerebro-spinal nervous system (both derived from the epiblast) they might find a clue as to the ready response of the latter when the former was stimulated by external agencies, i.e., thermal methods.—Dr. Leonard Williams (London) said that the thermal treatment was in reality the recognition of the importance of the excretory and other functions of the skin. All thermal methods stimulated this large and important organ, and these methods constituted in reality the only means available for producing such stimulation and maintaining it over long periods of time. Herein lay the secret of that efficacy of spa treatment in chronic disease which was now somewhat tardily attaining to that recognition which was its due.—Dr. G. H. Thompson (Buxton) wished to emphasise the importance of first using thermal water in preference to other methods of treatment in suitable cases. Every form of bath, douche, &c., should be available, but the simple immersion bath was often sufficient. At Buxton, by simple immersion, about 80 per cent. favourable results were obtained. The mode of action would probably be found to lie in the molecular activity of the various constituents of the water, such as radium, nascent gases, &c., which action was transmitted through the nerve endings to the various nerve centres and thence to the tissues.—In the evening the Fellows dined together at the Empire Hotel, the Mayor of Bath and Sir Thomas Chavasse (Birmingham) being guests of the society. The Fellows were afterwards present at a reception at the Pump Room given by the mayor and corporation of Bath, when the Roman Bath was illuminated.—On the following day (Sunday) the Fellows inspected the bathing establishments and then attended Divine service in the Abbey.—Later in the day the Fellows were received at Winsley Sanatorium by Dr. Lionel A. Weatherly who gave a lecture on the Results of the Open-air Treatment of Tuberculous Disease.—Mr. E. D. Townroe (resident medical officer), Dr. StClair Thomson (London), Sir Thomas Chavasse, Dr. W. J. Tyson (Folkestone), and the President took part in the discussion.—A vote of thanks was passed by the Fellows to the medical profession of Bath for their kind hospitality and Dr. Begg replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND: SECTION OF MEDICINE.—A meeting of this section was held on March 30th, Dr. George Peacocke being in the chair.—Dr. W. J. Thompson exhibited a case of Keratosis which had been under his care. The patient's personal and family history was good and before Christmas he was quite well. Then the palms of his hands and the soles of his feet became rough, thickened, and swollen. The inside of the mouth became very much swollen and the gums covered the teeth. His eyes were bloodshot. The skin thickened in the axilla and about the elbows and chest. All the openings of the body, ears, eyes, &c., were swollen; that of the nose sometimes became ulcerated and painful. There were no indications of derangement of the internal organs; the nervous system, reflexes, and thyroid gland were normal. He had been under thyroid treatment for the past three weeks with considerable benefit. His genital organs were completely atrophied.—Dr. Wallace Beatty said that he considered it to be an example of acanthosis nigricans and exhibited a plate illustrating the affection.—Dr. John M. Finny read notes on a case of Bradycardia with Arrhythmia and Epileptiform Fits which had been under observation for nine months and which ended fatally after very severe and prolonged fits of syncope. The patient was a seemingly healthy married woman, aged 42 years, the mother of three children, in whom there was no evidence of any cardiac or arterial disease or organic disease of any of the viscera. Her illness began 14 months before admission to hospital by a fit of unconsciousness, in which she fell, and which was followed by many similar slight syncopal attacks. She was delivered of a healthy child three months before being under Dr. Finny's care. The child died at the age of seven weeks from convulsions, and since his death the "weaknesses" had become more frequent—as many as 12 occurring in a day. The woman's pulse-rate on admission in June, 1905, and all

Musculo-spiral Paralysis. There had been a good recovery four months after operation.—Dr. W. R. Smith showed a patient with a Primary Chancre on the Lip.—Dr. F. H. Jacob showed a case of Ophthalmoplegia.—Mr. R. C. Chicken showed the following pathological specimens: (1) Hæmatosalpinx from a case of Pelvic Hæmatocele previously to Tubal Abortion; (2) Hæmatosalpinx from a case of Pelvic Hæmatocele during Tubal Abortion; (3) Ovary and Cyst from a case of Pelvic Hæmatocele due to Ruptured Hæmatosalpinx; (4) Hydrosalpinx; (5) Rectum removed by Kraske's operation for Carcinoma; and (6) Three Thickened Internal Alar Ligaments from so-called cases of "split semilunar cartilage."—Mr. Chicken also read a short paper entitled "A few Notes on Pelvic Hæmatocele."—Mr. Hogarth read a paper on the Causation, Diagnosis, and Treatment of Intussusception, based on a large number of cases on which he had operated during recent years. After drawing attention to the usual forms and giving notes of cases he described two cases in which the appendix vermiformis seemed to be the cause and formed (inverted) the apex of the intussusception. This was a condition which up to now had been overlooked or not recognised. The diagnosis from other conditions was fully discussed and the importance was pointed out of an early diagnosis before the occurrence of blood and mucus in the stools.—Dr. W. Hunter, Mr. W. Morley Willis, Dr. C. H. Cattle, Dr. Jacob, Dr. Thomson Henderson, Mr. Chicken, and others discussed the paper.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 6th, Mr. W. Campbell M'Donnell, the President, being in the chair.—Dr. H. P. Miller gave a demonstration of the following eye cases: 1. Markedly Opaque Nerve Fibres. 2. Old Trachoma which had been under treatment 12 months but was now nearly well. 3. Congenital Cataract with good vision after needling; the margin of the lens capsule could be seen. 4. Congenital Glaucoma, with deep anterior chambers. The eyes were enlarged and the corneæ bulging. 5. Glaucoma of the Right Eye, with deep anterior chamber and lenticular opacities. The tension was markedly plus and the vision nil. 6. Old Iritis, showing irregular pupil and atrophied iris. The eye was soft; the tension was minus and the vision nil. 7. Interstitial Keratitis, Cyclitis, and Keratitis Punctata. 8. Old Iritis, Cyclitis, and Episcleritis, for which iridectomy had been performed. 9. Adherent Leukoma from Corneal Ulcer. There was prolapse of the iris and the pupil was displaced from the adherent iris. 10. Left Corneal Ulcer, showing spots of infiltration in the cornea and deep anterior chamber. 11. Xerosis of Conjunctiva. 12. Tremulous Iris and Dislocation of Lens.—The following office-bearers were elected for the session 1906–07: President: Dr. J. R. T. Conner. Honorary secretary: Dr. David Ross. Honorary treasurer and curator: Dr. B. G. Morison. Council: Dr. W. Langdon Brown, Dr. Leslie Durno, Mr. G. Angus Hunt, Mr. W. Campbell M'Donnell, and Dr. J. S. Risien Russell.

NEWCASTLE-UPON-TYNE CLINICAL SOCIETY.—A meeting of this society was held on April 12th.—The following cases were shown:—Dr. J. Hudson: Syringomyelia.—Dr. D. W. Patterson: Cases of Lupus Erythematosus, Ichthyosis, Dermatitis Herpetiformis, and Morphœa, and illustrations of the Therapeutic Effects of X Rays in Dermatology.—Mr. T. G. Ouston: Thyrotomy for Papilloma three years after operation; case after Astragalectomy.—Mr. J. Clay: Tertiary Syphilitic Lesions; Stricture treated by External Urethrotomy; specimen of Tubal Abortion.—Mr. J. W. Leech: A series of cases of Malignant Disease—Specific Glossitis, a patient after operation for Thyroglossal Dermoid and varieties of Gall-stones.—The following officers were elected for next session, 1906–07.—President: Mr. W. H. Vickery. Vice-President: Mr. T. G. Ouston. Treasurer: Mr. G. G. Turner. Secretary: Mr. J. W. Leech. Committee: Mr. G. Foggin, Mr. J. Clay, Mr. W. Martin, Dr. M. N. Maclay, Dr. J. S. McCraken, Mr. T. H. Livingstone, Dr. R. A. Bolam, Dr. T. Beattie, Dr. W. Hardcastle, Dr. D. W. Patterson, Mr. H. B. Angus, and Dr. R. S. Hindmarch.

HUNTERIAN SOCIETY.—A meeting of this society was held on April 11th, Mr. John Poland being in the chair.—Mr. Jonathan Hutchinson opened a discussion on Syphilis and gave a most interesting account of the history of the disease and its treatment, and suggested some points which required elucidation.—Dr. G. H. Savage spoke on the Relation of Syphilis to Insanity.—Dr. J. Purves Stewart spoke on the Relation of Syphilis to some Diseases of the Central Nervous System and discussed the diagnosis of tabes and general paralysis of the insane by examination of the cerebro-spinal fluid.—Dr. W. Hale White spoke on Visceral Syphilis, illustrating his remarks by exhibition of museum specimens.—Mr. T. P. Beddoes also spoke.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on April 11th.—The following cases and specimens were shown. Dr. H Campbell Thomson: Cerebellar Tumour.—Mr. P. Macleod Yearsley: Specimens of Neoplasms of the External Ear.—Mr. C. Ryall: A case of Ileo-colostomy; specimen of Malignant Disease of the Rectum; and specimen of the Stomach and Intestine of an Infant with Congenital Absence of the Small Intestine.—Dr. S. Verdon Roe: Salivary Calculus.—Mr. E. J. Pritchard: A case of Absolute Loss of Voice for over a year.—Dr. J. T. Thyne: An Armless and Legless Man; and a case of Nævus of the Hand.—Dr. D. Kernohan: A case of Pernicious Anæmia.

Reviews and Notices of Books.

Criminal Statistics, England and Wales, 1904: Statistics relating to Criminal Proceedings, Police, Coroners, Prisons, Reformatory and Industrial Schools, and Criminal Lunatics, for the Year 1904. Edited by W. J. FARRANT. London: Wyman and Sons, Limited. Pp. 204. Price 1*s.* 7*d.*

AMONGST the official publications in this country that are of special interest to the student of sociology, the volume of criminal statistics which is issued annually by the Home Office may rank as one of the most important. The information which it embodies, referring, as it does, to the police returns of the amount and distribution of crime, to the proceedings of the several courts taking cognisance of criminal offences, to coroners' inquests, and to the populations of prisons, reformatories, and criminal lunatic asylums, presents a series of views of different and mutually illuminating aspects of the movement of crime which, taken together, form a complete guide to this department of *Moralstatistik.*

In the latest volume, which deals with the year 1904, the annual tables are arranged, except for some minor details, in the form adopted when the statistics were revised in 1892. As in previous issues they are preceded by a series of comparative tables illustrating the periodic variations in the amount of crime absolutely and relatively to population and the differences in its regional distribution. The general introduction, which is contributed by the editor, is confined this year to a summary of the principal figures,

In 1904 crime as a whole increased. The figures for the year, compared with the corresponding figures for 1903 and with the annual average for the five years 1900–04, show a distinct rise in the total volume of criminality, whether measured by the number of indictable offences reported to the police, by the number of persons tried or the number of persons convicted of such offences, or by the numbers of the prison population. The number of persons tried for indictable crimes, which is usually taken as the surest index of the movement of criminality, amounted in 1904 to 59,960, or 178 per 100,000 of population, the proportion in the previous year being 175 and in the quinquennial period 1900–04, 172 per 100,000. It thus appears that the growth of crime, which set in after 1899, following on a long period of steady decline, has not yet ceased. This way of stating the matter is, however, misleading, for it fails to take account of the fact that the term crime does not indicate any single and definite mode of conduct but is merely a general label for a heterogeneous collection of acts and omissions that have no common character save that of illegality. In reality, of course, the conditions that give rise to the several forms of

Musculo-spiral Paralysis. There had been a good recovery four months after operation.—Dr. W. R. Smith showed a patient with a Primary Chancre on the Lip.—Dr. F. H. Jacob showed a case of Ophthalmoplegia.—Mr. R. C. Chicken showed the following pathological specimens: (1) Hæmatosalpinx from a case of Pelvic Hæmatocele previously to Tubal Abortion; (2) Hæmatosalpinx from a case of Pelvic Hæmatocele during Tubal Abortion; (3) Ovary and Cyst from a case of Pelvic Hæmatocele due to *Ruptured Hæmatosalpinx*; *(4) Hydrosalpinx*; *(5) Rectum* removed by Kraske's operation for Carcinoma; and (6) Three Thickened Internal Alar Ligaments from so-called cases of "split semilunar cartilage."—Mr. Chicken also read a short paper entitled "A few Notes on Pelvic Hæmatocele."—Mr. Hogarth read a paper on the Causation, Diagnosis, and Treatment of Intussusception, based on a large number of cases on which he had operated during recent years. After drawing attention to the usual forms and giving notes of cases he described two cases in which the appendix vermiformis seemed to be the cause and formed (inverted) the apex of the intussusception. This was a condition which up to now had been overlooked or not recognised. The diagnosis from other conditions was fully discussed and the importance was pointed out of an early diagnosis before the occurrence of blood and mucus in the stools.—Dr. W. Hunter, Mr. W. Morley Willis, Dr. C. H. Cattle, Dr. Jacob, Dr. Thomson Henderson, Mr. Chicken, and others discussed the paper.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 6th, Mr. W. Campbell M'Donnell, the President, being in the chair.—Dr. H. P. Miller gave a demonstration of the following eye cases: 1. Markedly Opaque Nerve Fibres. 2. Old Trachoma which had been under treatment 12 months but was now nearly well. 3. Congenital Cataract with good vision after needling; the margin of the lens capsule could be seen. 4. Congenital Glaucoma, with deep anterior chambers. The eyes were enlarged and the corneæ bulging. 5. Glaucoma of the Right Eye, with deep anterior chamber and lenticular opacities. The tension was markedly plus and the vision nil. 6. Old Iritis, showing irregular pupil and atrophied iris. The eye was soft; the tension was minus and the vision nil. 7. Interstitial Keratitis, Cyclitis, and Keratitis Punctata. 8. Old Iritis, Cyclitis, and Episcleritis, for which iridectomy had been performed. 9. Adherent Leukoma from Corneal Ulcer. There was prolapse of the iris and the pupil was displaced from the adherent iris. 10. Left Corneal Ulcer, showing spots of infiltration in the cornea and deep anterior chamber. 11. Xerosis of Conjunctiva. 12. Tremulous Iris and Dislocation of Lens.—The following office-bearers were elected for the session 1906–07: President: Dr. J. R. T. Conner. Honorary secretary: Dr. David Ross. Honorary treasurer and curator: Dr. B. G. Morison. Council: Dr. W. Langdon Brown, Dr. Leslie Durno, Mr. G. Angus Hunt, Mr. W. Campbell M'Donnell, and Dr. J. S. Risien Russell.

NEWCASTLE-UPON-TYNE CLINICAL SOCIETY.—A meeting of this society was held on April 12th.—The following cases were shown:—Dr. J. Hudson: Syringomyelia.—Dr. D. W. Patterson: Cases of Lupus Erythematosus, Ichthyosis, Dermatitis Herpetiformis, and Morphœa, and illustrations of the Therapeutic Effects of X Rays in Dermatology.—*Mr. T. G. Ouston: Thyrotomy for Papilloma* three years after operation; case after Astragalectomy.—Mr. J. Clay: Tertiary Syphilitic Lesions; Stricture treated by External Urethrotomy; specimen of Tubal Abortion.—Mr. J. W. Leech: A series of cases of Malignant Disease—Specific Glossitis, a patient after operation for Thyroglossal Dermoid and varieties of Gall-stones.—The following officers were elected for next session, 1906–07.—President: Mr. W. H. Vickery. Vice-President: Mr. T. G. Ouston. Treasurer: Mr. G. G. Turner. Secretary: Mr. J. W. Leech. Committee: Mr. G. Foggin, Mr. J. Clay, Mr. W. Martin, Dr. M. N. Maclay, Dr. J. S. McCraken, Mr. T. H. Livingstone, Dr. R. A. Bolam, Dr. T. Beattie, Dr. W. Hardcastle, Dr. D. W. Patterson, Mr. H. B. Angus, and Dr. R. S. Hindmarch.

HUNTERIAN SOCIETY.—A meeting of this society was held on April 11th, Mr. John Poland being in the chair.—Mr. Jonathan Hutchinson opened a discussion on Syphilis and gave a most interesting account of the history of the disease and its treatment, and suggested some points which required elucidation.—Dr. G. H. Savage spoke on the Relation of Syphilis to Insanity.—Dr. J. Purves Stewart spoke on the Relation of Syphilis to some Diseases of the Central Nervous System and discussed the diagnosis of tabes and general paralysis of the insane by examination of the cerebro-spinal fluid.—Dr. W. Hale White spoke on Visceral Syphilis, illustrating his remarks by exhibition of museum specimens.—Mr. T. P. Beddoes also spoke.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on April 11th.—The following cases and specimens were shown. Dr. H Campbell Thomson: Cerebellar Tumour.—Mr. P. Macleod Yearsley: Specimens of Neoplasms of the External Ear.—Mr. C. Ryall: A case of Ileo-colostomy; specimen of Malignant Disease of the Rectum; and specimen of the Stomach and Intestine of an Infant with Congenital Absence of the Small Intestine.—Dr. S. Verdon Roe: Salivary Calculus.—Mr. E. J. Pritchard: A case of Absolute Loss of Voice for over a year.—Dr. J. T. Thyne: An Armless and Legless Man; and a case of Nævus of the Hand.—Dr. D. Kernohan: A case of *Pernicious* Anæmia.

Reviews and Notices of Books.

Criminal Statistics, England and Wales, 1904: Statistics relating to Criminal Proceedings, Police, Coroners, Prisons, Reformatory and Industrial Schools, and Criminal Lunatics, for the Year 1904. Edited by W. J. FARRANT. London: Wyman and Sons, Limited. Pp. 204. Price 1*s*. 7*d*.

AMONGST the official publications in this country that are of special interest to the student of sociology, the volume of criminal statistics which is issued annually by the Home Office may rank as one of the most important. The information which it embodies, referring, as it does, to the police returns of the amount and distribution of crime, to the proceedings of the several courts taking cognisance of criminal offences, to coroners' inquests, and to the populations of prisons, reformatories, and criminal lunatic asylums, presents a series of views of different and mutually illuminating aspects of the movement of crime which, taken together, form a complete guide to this department of *Moralstatistik*.

In the latest volume, which deals with the year 1904, the annual tables are arranged, except for some minor details, in the form adopted when the statistics were revised in 1892. As in previous issues they are preceded by a series of comparative tables illustrating the periodic variations in the amount of crime absolutely and relatively to population and the differences in its regional distribution. The general introduction, which is contributed by the editor, is confined this year to a summary of the principal figures,

In 1904 crime as a whole increased. The figures for the year, compared with the corresponding figures for 1903 and with the annual average for the five years 1900–04, show a distinct rise in the total volume of criminality, whether measured by the number of indictable offences reported to the police, by the number of persons tried or the number of persons convicted of such offences, or by the numbers of the prison population. The number of persons tried for indictable crimes, which is usually taken as the surest index of the movement of criminality, amounted in 1904 to 59,960, or 178 per 100,000 of population, the proportion in the previous year being 175 and in the quinquennial period 1900–04, 172 per 100,000. It thus appears that the growth of crime, which set in after 1899, following on a long period of steady decline, has not yet ceased. This way of stating the matter is, however, misleading, for it fails to take account of the fact that the term crime does not indicate any single and definite mode of conduct but is merely a general label for a heterogeneous collection of acts and omissions that have no common character save that of illegality. In reality, of course, the conditions that give rise to the several forms of favour of the oily solutions of the alkaloids. He rightly points out in the first place that aqueous collyria are not easy to administer satisfactorily. Their instillation often gives rise to profuse lacrymation and blepharospasm, thereby rendering the local effect of the application very uncertain and often abortive. At the same time, excess of the lotion may be easily carried over the cheek into the mouth, or it may reach the œsophagus through the lacrymal duct and pharynx and set up symptoms of poisoning by absorption. All these difficulties are avoided by the use of the oily collyria. They can be instilled into the eye accurately drop by drop without exciting any lacrymation or spasm, and the drops are quickly diffused over the surface of the eyeball, producing the desired effect with precision and rapidity. By comparative experiments on animals Dr. Scrini was able to show, by dropping an aqueous solution into one eye and an oily solution into the other, that the effect of the latter appeared more rapidly and lasted longer. Oily solutions have the further great advantage that they remain sterile, whereas the aqueous collyria of the alkaloids become easily infected with micro-organisms. Moreover, eserine readily decomposes in water, forming an irritating product known as *rubreserine* on account of the rose-red colour which it gives to the solution. No such decomposition takes place in oil. Ointments share with the oily collyria many of the advantages over aqueous solutions but they are liable to set up irritation on account of the fatty acids of decomposition which they may contain. Of the many oils which may be employed Dr. Scrini gives the preference to olive oil. Castor oil and almond oil irritate the conjunctiva and hydrocarbon oils do not dissolve the alkaloids in sufficient strength. In all cases the alkaloid base must be used. The oil should be first shaken with alcohol, decanted, and sterilised by heating to 120° C. Oily collyria have not received much favour in this country on account of the natural objection to the use of oily materials and their liability to soil the clothing of the patient. But there is also a serious objection to the use of homatropine in oily solution, as an oily film is formed over the cornea, which persists for some time and renders retinoscopic observations very difficult. The employment of a fatty or oily menstruum or vehicle for the application of remedial agents to the eye is no new thing. Perhaps the most commonly used medicament that is on the table of every ophthalmic surgeon is the binoxide of mercury and this is almost always made up with vaseline or with lard or glycerine or lanoline. Iodoform, as well as the various mydriatics and myotics, are not infrequently employed in the same manner. The chief objection to oil is its liability to become rancid owing to the formation by oxidation of the fatty acids. In Italy and France, where perfectly fresh olive oil can easily be obtained, this objection may not hold, but in this country such oil is not procurable and pomades or ointments so made would prove both irritating and painful to eyes already inflamed.

International Clinics. Edited by A. O. J. KELLY, A.M., M.D., Philadelphia. Vol. IV., Fourteenth Series. London and Philadelphia: J. B. Lippincott Company. 1905. Pp. 314.—A vigorous protest against the excessive use of drugs in the treatment of chronic diseases, with reference to medicinal intoxication, comes from Dr. George Hayem, and his conclusions in favour of "hygienic modifiers" when specific or serotherapeutic agents are useless must be regarded as the outcome of a certain disappointment with the results of pure empiricism; but is he not flogging a dead horse? There are few who would in these days admit that their treatment is *empirical*, though probably many share with him the distrust of the excessive use of drugs, a habit which is to a great extent to be laid at the doors of those of the public who assume the responsibility of prescribing for themselves. Dr. Adolphe Javal of Paris deals with the indications for the dechloridation treatment in an article which perplexes by its combination of French and American spelling of many chemical and technical terms. The value of radium in the treatment of lupus, rodent ulcer, and epithelioma is illustrated by numerous figures and it is claimed that good results have been obtained with it, though it is admitted that sufficient time has not elapsed to permit of claims for a permanent cure. Professor Senator deals with the clinical significance of albumosuria and maintains that if albuminous urine is boiled for a long time albumoses may be formed from the albumin. This volume also includes interesting lectures upon functional heart murmurs, upon several surgical subjects, and upon amœbic infection of the intestine and liver.

First Aid to the Injured and Sick. By F. J. WARWICK, B.A., M.B. Cantab., M.R.C.S. Eng., late Captain R.A.M.C., and A. C. TUNSTALL, M.D., F.R.C.S. Edin. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1906. Pp. 242. Price, paper, 1*s.*; cloth, 2*s.*—We have received a copy of the fourth edition of this useful little handbook, which contains all the information necessary for the instruction of an advanced ambulance class. The text of this edition has been thoroughly revised by the authors, both of whom are experienced ambulance lecturers, and illustrations have been added to the chapters on Digestion and Excretion which must help to explain to first-aid students subjects which they necessarily find very difficult. We have nothing but praise for an excellent and practical little manual, but the authors might take an early opportunity of giving the artist who drew their ornamental cover a hint or two on anatomy.

Materia Medica and Therapeutics. By J. MITCHELL BRUCE, M.A., LL.D. Aberd., M.D. Lond. London: Cassell and Company. 1905. Pp. 632. Price 7*s.* 6*d.*—This appears to be the seventh edition of this text-book, or the sixth occasion on which it has been revised; at any rate, on the title-page it is indicated that it is the forty-seventh thousand and accordingly the task of the reviewer is light, since the book has made its mark and needs no words of commendation. There are, however, some new features which deserve mention. The size has been increased owing to the inclusion of an account of the materia medica and therapeutics of the drugs in the Indian and Colonial Addendum to the British Pharmacopœia and to the introduction of greater detail respecting the chemical and pharmaceutical relations of the individual drugs. The Indian and Colonial additions are grouped together and placed in alphabetical order, an arrangement which, it may be hoped, will facilitate certain omissions which appear to be desirable, to judge from the small amount of information respecting their actions and uses. On two pages in this section (p. 444 and p. 445) the omission of the line ordinarily used between paragraphs relating to different drugs may give rise to momentary confusion of thought. In the parts relating to the drugs employed in this country space has been found for the inclusion of many new remedies which are not official, such as urotropine, trional, veronal, aspirin, and citarin. The relative importance of these substances is not to be gauged by the relative amount of space allotted to them. Mention has already been made of the greater attention to the chemical relations in this edition; this is necessarily shown to greatest advantage in connexion with the carbon compounds, but it may be regretted that the author has not adopted a consistent plan; as examples may be cited the representations of the composition of sulphonal and of phenazonum which occur on the same page. In spite of the minor blemishes referred to there can be no doubt that this book merits the favour with which it has been received by successive generations of students and it may be further stated

Victor Cox Pedersen who holds many appointments in New York and who states in his preface that it is intended that the series, as a whole, should embrace the entire realm of medicine and that in the individual volumes the maximum of information in letterpress and engravings should be given for a minimum price. This volume contains no engravings, hence the letterpress must be more costly than in other illustrated volumes of the series. There is no list of the other volumes included in that at present under consideration but one on Diseases of the Nose and Throat is mentioned in the author's preface, while another on Diseases of the Nervous System is referred to in the section on Tuberculosis. The classification of Osler has been followed closely throughout and the material has been arranged systematically under each disease in the familiar form of definition, etiology, pathology, symptoms, complications and sequelæ, diagnosis, prognosis, and treatment. The marvel is that within the space so much information is compressed. It is stated that the work is intended for "hasty reference" by practitioners, as well as for the use of students. For hasty reference it appears to be admirable; for the use of students revising in a hurry before an examination it may be of service, but we would warn all others that the attempt to study medicine in this condensed form will be speedily provocative of a kind of mental shortness of breath. The book is obviously a skilful compression of one or more larger works and the facts are accurate and represent recent advances but, perhaps because of its Transatlantic origin, it inevitably suggests the idea of the quick luncheons which we owe to the same source and it is very filling at the price. Personally we prefer a more leisurely meal.

The Physiology and Therapeutics of the Harrogate Waters, Baths, and Climate Applied to the Treatment of Chronic Disease. By WILLIAM BAIN, M.D. Durh., and WILFRID EDGECOMBE, M.D. Lond. London: Longmans, Green, and Co. 1905. Pp. 300. Price 7*s*. 6*d*. net.

AN attempt is here made to supply evidence showing that the therapeutics of the local waters and baths rest on a secure foundation comparable to that of drug therapeutics. Separate sections are devoted to the waters, baths, and climate, and in each section members of the medical profession, for whom the book has been written, will find much that is instructive. In the first section upon the pharmacology and therapeutics of the natural mineral waters the authors acknowledge their indebtedness to Professor T. G. Brodie for many helpful suggestions and it will be remembered that the same writer contributed the physiological sections in the text-book of medical practice edited by Dr Bain and favourably reviewed in these columns.

Many will be surprised to learn that Harrogate possesses no less than 80 springs of different chemical constitution and that about 16 of these are used internally, the remainder being devoted to bathing purposes. In contrast to some of the continental spas, it is openly admitted that in their natural state the waters are athermal and that they are heated artificially. Speaking in general terms, a saline constituent is common to all, together with other compounds either of sulphur or of iron. This permits of their classification into two divisions: (1) saline-sulphur waters; and (2) saline-chalybeate waters, each again being subdivided into strong, medium, or mild according to the amount of solids present. Considering the waters individually, the first place is assigned to the Old Sulphur Spring which is regarded as being unquestionably the most valuable water which Harrogate possesses. The authors describe its pharmacology and give tables showing its influence upon the excretion of urea, of uric acid, and of sulphates. The effects on the blood and upon the function of the liver are also demonstrated by charts and tables which represent the results of many experimental researches. The authors state that they believe that the value of the water would be enhanced if it contained less hydrogen sulphide, and without venturing to question this belief many for whom this water has been prescribed will agree that it would be more readily taken if this ingredient could be reduced or if its presence could be rendered less aggressively obvious. Considering the importance of the water the account of its therapeutic action appears somewhat meagre and unconvincing; there is not much guidance in the statement that "the water is prescribed with varying degrees of success" in seven or eight conditions which are here enumerated. The composition of each of the other mineral waters is considered in turn and to each are assigned a paragraph on pharmacology and one on therapeutics; frequently a chemical analysis of some 20 years ago is followed by a skeleton analysis of recent date and thus an opportunity is afforded of judging the slight variations in composition which have occurred during the interval. The classification of the baths of Harrogate is sufficient to demonstrate the vigour with which the supply has been made to meet the demand: there are thermal baths, thermo-chemical baths, thermo-mechanical baths, thermo-electric baths, and electric baths, and the number included under each of these headings brings up the total to a high figure. The thermo-chemical baths are, of course, those which may be regarded as belonging specially to Harrogate; it is, however, useful to have in these pages a general account of the physiological action of baths and of their therapeutic uses.

Special pleading is to be expected so soon as the climate of a health resort is approached. We do not for one moment doubt the accuracy of the figures in all the tables relating to the meteorological data (they have been supplied by the meteorologist to the Harrogate corporation) but it is impossible not to feel that the districts and towns selected for purposes of comparison seem to have been chosen rather arbitrarily. They vary in the different tables and Harrogate nearly always appears to advantage under this system of comparison.

The fourth section gives an interesting analysis of cases sent to Harrogate for spa treatment; conditions termed "gout and goutiness" head the list, and they are closely followed by skin diseases of undefined nature, while forms of rheumatism, diseases of the liver, neurasthenia, and diseases of the stomach also account for considerable numbers of visitors. This list in round numbers accounts for four-sevenths of the visitors, the remaining three-sevenths coming with no less than 41 different types of disease. This concluding section on the treatment of chronic disease is necessarily rather brief, since the authors have rigorously excluded reference to individual cases but none the less it opens up vistas of hope for numbers who are depressed by the torments of chronic maladies. The authors repeatedly remark that each case should be treated on its merits and this wise reserve is far more likely to be productive of benefit than if they had been unduly optimistic. They are to be congratulated upon the success with which they have vindicated the favourable attitude which they maintain towards the spa treatment of chronic disease.

LIBRARY TABLE.

De l'Emploi des Alcaloïdes en Solution Huileuse. (*On the Employment of Alkaloids in Oily Solution.*) By Dr. SCRINI. Paris: Vigot Frères. 1906. Pp. 108. Price Fr. 2.50.—It is already well known to ophthalmic surgeons in this country that oily solutions of the alkaloids possess certain advantages over the aqueous solutions as collyria but they have not received general adoption except perhaps in the case of eserine. In this monograph Dr. Scrini sets forth in detail the reasons which have led him to abandon all other forms of collyria, especially aqueous solutions and ointments, in favour of the oily solutions of the alkaloids. He rightly points out in the first place that aqueous collyria are not easy to administer satisfactorily. Their instillation often gives rise to profuse lacrymation and blepharospasm, thereby rendering the local effect of the application very uncertain and often abortive. At the same time, excess of the lotion may be easily carried over the cheek into the mouth, or it may reach the œsophagus through the lacrymal duct and pharynx and set up symptoms of poisoning by absorption. All these difficulties are avoided by the use of the oily collyria. They can be instilled into the eye accurately drop by drop without exciting any lacrymation or spasm, and the drops are quickly diffused over the surface of the eyeball, producing the desired effect with precision and rapidity. By comparative experiments on animals Dr. Scrini was able to show, by dropping an aqueous solution into one eye and an oily solution into the other, that the effect of the latter appeared more rapidly and lasted longer. Oily solutions have the further great advantage that they remain sterile, whereas the aqueous collyria of the alkaloids become easily infected with micro-organisms. Moreover, eserine readily decomposes in water, forming an irritating product known as *rubréserine* on account of the rose-red colour which it gives to the solution. No such decomposition takes place in oil. Ointments share with the oily collyria many of the advantages over aqueous solutions but they are liable to set up irritation on account of the fatty acids of decomposition which they may contain. Of the many oils which may be employed Dr. Scrini gives the preference to olive oil. Castor oil and almond oil irritate the conjunctiva and hydrocarbon oils do not dissolve the alkaloids in sufficient strength. In all cases the alkaloid base must be used. The oil should be first shaken with alcohol, decanted, and sterilised by heating to 120° C. Oily collyria have not received much favour in this country on account of the natural objection to the use of oily materials and their liability to soil the clothing of the patient. But there is also a serious objection to the use of homatropine in oily solution, as an oily film is formed over the cornea, which persists for some time and renders retinoscopic observations very difficult. The employment of a fatty or oily menstruum or vehicle for the application of remedial agents to the eye is no new thing. Perhaps the most commonly used medicament that is on the table of every ophthalmic surgeon is the binoxide of mercury and this is almost always made up with vaseline or with lard or glycerine or lanoline. Iodoform, as well as the various mydriatics and myotics, are not infrequently employed in the same manner. The chief objection to oil is its liability to become rancid owing to the formation by oxidation of the fatty acids. In Italy and France, where perfectly fresh olive oil can easily be obtained, this objection may not hold, but in this country such oil is not procurable and pomades or ointments so made would prove both irritating and painful to eyes already inflamed.

International Clinics. Edited by A. O. J. KELLY, A.M., M.D., Philadelphia. Vol. IV., Fourteenth Series. London and Philadelphia: J. B. Lippincott Company. 1905. Pp. 314.—A vigorous protest against the excessive use of drugs in the treatment of chronic diseases, with reference to medicinal intoxication, comes from Dr. George Hayem, and his conclusions in favour of "hygienic modifiers" when specific or serotherapeutic agents are useless must be regarded as the outcome of a certain disappointment with the results of pure empiricism: but is he not flogging a dead horse? There are few who would in these days admit that their treatment is empirical, though probably many share with him the distrust of the excessive use of drugs, a habit which is to a great extent to be laid at the doors of those of the public who assume the responsibility of prescribing for themselves. Dr. Adolphe Javal of Paris deals with the indications for the dechloridation treatment in an article which perplexes by its combination of French and American spelling of many chemical and technical terms. The value of radium in the treatment of lupus, rodent ulcer, and epithelioma is illustrated by numerous figures and it is claimed that good results have been obtained with it, though it is admitted that sufficient time has not elapsed to permit of claims for a permanent cure. Professor Senator deals with the clinical significance of albumosuria and maintains that if albuminous urine is boiled for a long time albumoses may be formed from the albumin. This volume also includes interesting lectures upon functional heart murmurs, upon several surgical subjects, and upon amœbic infection of the intestine and liver.

First Aid to the Injured and Sick. By F. J. WARWICK, B.A., M.B. Cantab., M.R.C.S. Eng., late Captain R.A.M.C., and A. C. TUNSTALL, M.D., F.R.C.S. Edin. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1906. Pp. 242. Price, paper, 1*s.*; cloth, 2*s.*—We have received a copy of the fourth edition of this useful little handbook, which contains all the information necessary for the instruction of an advanced ambulance class. The text of this edition has been thoroughly revised by the authors, both of whom are experienced ambulance lecturers, and illustrations have been added to the chapters on Digestion and Excretion which must help to explain to first-aid students subjects which they necessarily find very difficult. We have nothing but praise for an excellent and practical little manual, but the authors might take an early opportunity of giving the artist who drew their ornamental cover a hint or two on anatomy.

Materia Medica and Therapeutics. By J. MITCHELL BRUCE, M.A., LL.D. Aberd., M.D. Lond. London: Cassell and Company. 1905. Pp. 632. Price 7*s.* 6*d.*—This appears to be the seventh edition of this text-book, or the sixth occasion on which it has been revised; at any rate, on the title-page it is indicated that it is the forty-seventh thousand and accordingly the task of the reviewer is light, since the book has made its mark and needs no words of commendation. There are, however, some new features which deserve mention. The size has been increased owing to the inclusion of an account of the materia medica and therapeutics of the drugs in the Indian and Colonial Addendum to the British Pharmacopœia and to the introduction of greater detail respecting the chemical and pharmaceutical relations of the individual drugs. The Indian and Colonial additions are grouped together and placed in alphabetical order, an arrangement which, it may be hoped, will facilitate certain omissions which appear to be desirable, to judge from the small amount of information respecting their actions and uses. On two pages in this section (p. 444 and p. 445) the omission of the line ordinarily used between paragraphs relating to different drugs may give rise to momentary confusion of thought. In the parts relating to the drugs employed in this country space has been found for the inclusion of many new remedies which are not official, such as urotropine, trional, veronal, aspirin, and citarin. The relative importance of these substances is not to be gauged by the relative amount of space allotted to them. Mention has already been made of the greater attention to the chemical relations in this edition: this is necessarily shown to greatest advantage in connexion with the carbon compounds, but it may be regretted that the author has not adopted a consistent plan; as examples may be cited the representations of the composition of sulphonal and of phenazonum which occur on the same page. In spite of the minor blemishes referred to there can be no doubt that this book merits the favour with which it has been received by successive generations of students and it may be further stated that infinite pains have been taken to make the book a safe guide for students and a convenient work of reference for practitioners. It is 22 years since the publication of the first edition and yet, from the freshness of style and from the assimilation of recent work, the book still presents an air of youthful vigour.

JOURNALS AND MAGAZINES.

The Bristol Medico-Chirurgical Journal.—The March number opens with a full and interesting paper on Anti-tuberculous Vaccines and Sera, by Dr. J. M. Fortescue-Brickdale. He notes that about 20 of such specific remedies have been prepared and tried, but the results are on the whole small. Tuberculin is, however, regaining some measure of favour and Marmorek's serum has given some encouraging results. Dr. J. J. S. Lucas deals with the Prognosis of Pulmonary Tuberculosis and Dr. P. Watson Williams with Defective Nasal Respiration. Dr. J. R. Charles discusses the Effects of Fright in Medicine and cases of Acute Yellow Atrophy of the Liver are recorded by Dr. F. H. Edgeworth and by Dr. Bertram M. H. Rogers.

The Edinburgh Medical Journal (April).—Mr. H. Alexis Thomson writes an interesting article on Brodie's Abscess of Bone; a table of cases shows that the condition occurs in the head of the tibia in more than one-third of all cases. The bacterium at work is generally streptococcus aureus, but streptococcus albus and bacillus typhosus also occur. Another surgical paper of importance is that by Mr. Alexander Miles on Epigastric Hernia (incidentally we may be permitted to wonder whether the spelling ziphisternum here occurring is a misprint or the latest Americanism). Dr. A. Haig once more affirms his belief in the toxicity of uric acid and its importance in gout, as well as in the scheme of diet which he has elaborated to combat the poison. A case of Leukanæmia is recorded by Dr. F. G. Bushnell and Dr. Donald G. Hall and one of Keratosis of the Larynx by Mr. A. Logan Turner.

The Scottish Medical and Surgical Journal (April).—This number opens with the Presidential Address delivered by Mr. George Rose to the Aberdeen Medico-Chirurgical Society on Acute Disease of Bone in Children. Mr. Charles W. Cathcart writes on the Treatment of Acute Inflammation by Bier's method of passive congestion, attributing part at least of the good effects produced to changes in arterial blood-pressure and claiming that this method cures early stages of inflammation before suppuration has developed and limits this process when it has occurred. Dr. W. G. Aitchison Robertson writes in praise of Uhlenhuth's precipitin test for blood-stains, and a special article is contributed by Dr. Edwin Bramwell on the Colony System of Treating Epileptics.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S.; D. J. CUNNINGHAM, M.D., F.R.S.; G. S. HUNTINGTON, M.D.; A. MACALISTER, F.R.S.; and J. G. M'KENDRICK, F.R.S. Vol. XL. Third Series, Vol. I., Part 3. With Plates and Illustrations in the Text. London: Charles Griffin and Company. 1906. Pp. 115. Published quarterly at 6*s.* each part.—1. The first article in this number is on the Surgical Anatomy of the Prostate, by J. W. Thomson Walker, F.R.C.S. Eng. The author gives a careful description of the sheath of the prostate or the fascia in which the prostate lies as an egg fills an egg cup, except at the apex, where the fascia becomes incorporated with the striped muscle surrounding the urethra. The relation of the prostate to the base of the bladder is then given, with drawings showing the appearances presented on section. The striped muscle of the prostate, the prostatic plexus of veins, the prostatic urethra, the arrangement of the gland tissue, and the seminal vesicles are successively considered and are illustrated by excellent drawings. 2. On the Anatomy of the Calamus Region in the Human Bulb, with an account of a hitherto undescribed "Nucleus Postremus," by J. T. Wilson, professor of anatomy in the University of Sydney, N.S.W. This article is a valuable contribution, with accurate illustrations, to our knowledge of a rather neglected portion of cerebral anatomy. 3. Notes on the Coronal Suture, by F. G. Parsons. 4. A Note on the Topographical Anatomy of the Caput Gyri Hippocampi, by Johnson Symington, F.R.S. 5. The Vermiform Appendix of Man and the Structural Changes therein Coincident with Age, by Richard J. A. Berry, F.R.S. Edin., and L. A. H. Lack, M.B. Edin., an able contribution to this subject which we have fully considered in another column. 6. Experimental Contribution to a Theory of Thinking, by Henry J. Watt, M.A., Ph.D., Carnegie Fellow. In these experiments several hundred nouns of common occurrence were printed in big type on cards and were shown to the observing subject one at a time by means of Dr. Ach's automatic card changer; a metal plate which covered the card sprang up when a string was pulled and by so doing closed an electric current which flowed through a Hipp chronoscope and a Cattell's speaking-tube. The chronoscope, therefore, marked the time which passed from the appearance of the printed word until the first vibrations from the subject's voice broke the current in the speaking-tube. This constituted the measure of the reaction and formed, with a full account of all the reproducible experiences of the observing subject which were at once written down, the experimental data of the thesis. Definite tasks were given in each experiment which the subject had to accomplish in the reaction, such as the classification of the printed word, the naming of an example of it, or of its parts, or of some other animal, plant or object in the same group. The results, too long to be here abstracted, are interesting and deserve the attention of psychologists. 7. On Some Minor Markings on Bones, by J. Ernest Frazer, F.R.C.S. Eng. 8. On the Presence of Elastic Fibres in the Cornua, by J. Hamilton M'Ilroy, M.B., B.Sc., Carnegie research scholar. 9. A report (sixteenth) on Recent Teratological Literature, by Bertram C. A. Windle, M.D. Dub., F.R.S. 10. An Unusual Displacement of the Heart, by David Waterston, M.A., M.D. Edin. The displacement was met with in a teal (Querquedula).

Looking Back.

FROM
THE LANCET, *SATURDAY*, April 19th, 1828.

EPIGRAM

On the Patient who suddenly decamped from Guy's Hospital.[*]

When Cooper's *nevey* cut for stone,
His toils were long and heavy;
This patient quicker parts has shown,
He *soon out* Cooper's *nevey.*[1]

[1] The accusation of malpraxis against Mr. Bransby Cooper made in THE LANCET, and on which this epigram was founded, resulted in his bringing a well-known libel action against the Editor.

THE official Asses of Guy's Hospital, have posted the following sensible notice at the Lodge. If these worthies are really desirous of a contest with the Press, let them come on—

"And damn'd be he that first cries, hold, enough.";

Guy's Hospital, April 8, 1828.

Order,—That, in consequence of untrue and unprofessional statements, relating to this Hospital, having appeared in THE LANCET, no person who reports for, or is in any way connected with that publication, shall be at liberty to attend the practice, or the schools of this Hospital.

JAMES BROWELL, Steward.

Hospital Management.

The essay on the Economical Management of an Efficient Voluntary Hospital, by Mr. G. H. Hamilton, to which the prize of £100 and a silver cup offered by Mr. E. Speyer has been awarded, and the essay upon the same subject by Mr. E. W. Morris, which was placed next in order of merit and for which its author received a special prize of £50, have been published in pamphlet form at the modest price of 6*d.* and, taken together, may be assumed to contain all that two hospital secretaries of great experience have thought it necessary to say upon the subject which has exercised their thoughts and pens. Mr. Hamilton, we need hardly add, is secretary to the National Hospital for the Paralysed and Epileptic, which a few years ago was the scene of a successful struggle on the part of the medical staff to obtain a proper share in its management; and Mr. Morris is secretary to the London Hospital, which, under the skilful and energetic control of the Hon. Sydney Holland, has for many years set an example to other institutions of like kind in the directions both of successful money-getting and of enlightened expenditure. It may be that having regard to the terms and conditions under which Mr. Speyer's prize was offered for competition the prize has gone to the right quarter, but if literary style counted we should be inclined to reverse the verdict of the judges and to give the first place to the essay by Mr. Morris. For in our opinion Mr. Hamilton is diffuse in his treatment of the obvious and not happy in his modes of expression.

A considerable part of the ground covered by both essays is connected with hospitals merely in relation to their economical management as large residential institutions and possesses no special interest for medical readers It is manifestly true, for example, that "boilers should be insured with a first-class boiler insurance company," and that, in relation to stores, while "economy in purchase is only one aspect of the matter economy of use is probably of greater importance still." Such observations, and several pages are occupied by them, would be as pertinent to the case of a school or college as to that of a hospital and need no special consideration from us. We may note in passing Mr. Hamilton's decided opinion that "a lady housekeeper should have the reception and distribution of all articles of food, linen, hardware, crockery, and cleansing materials," and, further, that this lady should be a "fully trained nurse, and, if possible, one who has been a ward sister." He believes that the success of such an arrangement would be due greatly to the fact that such an officer would have become aware of the circumstances in which, without any dishonest motive, excessive supplies of food or other articles were likely to be requisitioned; and he appears also to think, if we read between the lines, that a lady of the suggested qualifications would be less amenable than an average house steward to the possible blandishments of contractors and tradesfolk. There are probably few housekeepers, with experience in the ordinary domestic catering of private life, who will not be inclined to agree with him. The subjects of special medical interest dealt with in the essays are hardly more than two in number—namely, the share in the government of a hospital which should be allotted to the medical profession and the conditions which should regulate the admission of patients. With regard to the former of these questions, it must be remembered that Mr. Hamilton's predecessor in office was a gentleman who opposed strongly the demands of the medical staff of his hospital to secure a share in its management, and who desired to keep them in what was virtually the position of servants to a board of lay governors, although this interpretation was verbally denied. The question was thoroughly debated both in the press and at meetings and the complete victory of the medical staff led to the vacancy in the secretariat which Mr. Hamilton has since filled with much credit and distinction. He may therefore be expected to advocate a system to which, in fact, he is indebted for his position; and he does so, but with the curious limitation of objecting to a scheme of promotion which might render paid medical officers in the first place members of the honorary staff and ultimately representatives of their colleagues on the board of management. They would then, he says, "become masters of other permanent officers with whom they had at one time worked as colleagues, and such a condition of affairs might easily be undesirable." He proposes as a remedy for this imaginary evil that only honorary officers of long standing should be elected to the board, apparently with the notion that they would have survived their old colleagues We cannot but regard the objection as visionary and the remedy as worse than the evil which it is designed to prevent. An element of youth is conducive to the vigour of all administration, and the promotion of colleagues to be superiors is an incident of daily occurrence in connexion with the public services of the country. The question is one with which Mr. Morris has not thought it necessary to deal and which, as far as we know, has never occasioned trouble at the London Hospital, where the staff has always furnished important elements to the board and has always been considered and consulted in relation to the introduction of changes or reforms.

With regard to the admission of patients, the views entertained by Mr. Morris appear to us to be both more enlightened and more accurate than those of Mr. Hamilton. The latter gentleman defines the "primary object" of most hospitals to be "the medical and surgical relief of necessitous persons," and scarcely appears to carry his thoughts at all beyond the limitations which this definition would impose. Mr. Morris declares that "some" hospitals (may we not say nearly all?) have a loftier aim and take a broader view. "They are not content with simply returning their patients cured or relieved. They not only attempt to cure the disease from which the patient is suffering but they wish to investigate that disease, to trace it to its cause, to discover what favours it, what destroys it. ...... It will be one of *these* hospitals which will give to the world one of these days the discovery of the cause of cancer." With this absolute divergence of view between the two writers it is not surprising that Mr. Hamilton says, "In a hospital with ideal management, no patient will be treated for mere clinical interest," and that he entirely omits such matters as clinical and pathological laboratories from his account of the legitimate sources of expenditure. Mr. Morris, on the contrary, declares that the hospitals which he puts into his higher class must have "their bacteriological laboratories, clinical laboratories, pathological laboratories, physiological laboratories, sterilising rooms, &c., and all these adjuncts to research require a large staff and expensive material." He also points out the error of regarding the work of a "cheap" hospital as equal to that of an "expensive" one because the death-rate is the same. He mentions it as "a curious fact" that the death-rate of most hospitals is about 10 per cent. of the admissions and, happily, suggests as a proper test of efficiency the condition of the other 90 per cent. five years after they have been discharged. He even goes further and points out that the hundreds of people who never have to go to a hospital at all may owe their good fortune in this respect to the work in which his hospitals of the higher class have been, and are, continually engaged. In this relation, however, neither of the two writers takes note of the value to the community of the medical school. There can be no possible question that on any given day the work of healing or of prevention accomplished by the aggregate number of practitioners who have gone out from the school of any great hospital must far exceed that which is done within the walls of the hospital itself and that, whatever may be the value of the hospital to individuals, it is the school that is of transcendent value to the community. We therefore think it a matter for regret that the narrow views of hospital utility entertained by Mr. Hamilton in his practical essay should have been stamped with approval by the judges and we must express our absolute dissent from them. On the question of the fitness of patients for admission to hospital we obtain no effective guidance from either writer, and the recently suggested remedy for admitted evils which, it is by some contended, would be furnished by an adequate supply of properly organized "pay hospitals" did not fall perhaps within the scope of the conditions by which both essayists were bound. We should have been glad to hear their views upon this element in the hospital administration of the future, because it is obviously one upon which their duties and position would enable them to throw light, and as to which Mr. Morris at least must have been almost compelled to consider the recent publications of his chairman.

◆

The Registrar-General's Annual Report.

On the eve of going to press we have received a copy of the annual report for 1904 of the Registrar-General of England. Although its publication is somewhat belated our experience of previous issues inclines us to welcome the present volume which a very cursory perusal leads us to believe will rank as a valuable further contribution to the literature of demography. This report embodies the results of an ably conducted inquiry into the intricate causes which in recent years have produced far-reaching changes in the constitution and environment of the English people—changes by which their general welfare has been powerfully affected either for good or for evil. The present report fully sustains the high standard of those previously issued by Sir William Dunbar. It contains, however, sundry new features and to some of these we now propose more especially to refer. In his opening remarks the Registrar-General devotes considerable care to a scrutiny of the birth-rate which in this country, as well as in most others, is known to be falling continuously. The mutual relations of the marriage- and birth-rates, and of the latter with the death rates, are discussed with remarkable fairness and skill, and so great is the importance which is attached to this subject that twenty pages at least are devoted to its consideration. Within the space at our disposal we can do no more than indicate briefly the more important conclusions arrived at in this report. We wish, however, that its circulation could by some means be widely extended or, better still, that certain portions of it could be reproduced in a less compendious form, so that the subjects treated of might come within reach of the general reader who for the most part eschews everything of the nature of a Blue-book. In this and in other European countries variations in the marriage-rate are known to correspond to variations in economic conditions of highly complex character which cannot be considered here. The method hitherto adopted of registering variations in the rate of marriage is by stating the ratio of persons married to the population at all ages. But a more accurate result can be obtained by calculating the marriages on the unmarried and widowed portion of the population above the age of 15 years, thus dealing with that section of the people among whom alone marriages take place. Reckoned in this way the English marriage-rate has decreased progressively throughout the last 35 years, the total fall within that period being equivalent to 19 per cent. Surrey, Middlesex, and Essex are the only English counties in which the marriage-rates have increased at all. In London there has been a decrease of 21 per cent. In 14, mainly agricultural, counties the rate has fallen by from 2 to 9 per cent., whilst in the remaining counties the decrease has ranged from 10 to as much as 29 per cent. An interesting table appears in the report showing that, relatively to the total population, the marriage-rates in seven European countries averaged from 1 to 23 per cent. above the rates of England and Wales, whilst in eight other European countries the rates ranged from 1 to 37 per cent. below the English rate. Within the last 35 years the rate of births in this country, calculated on the married female population aged from 15 to 45 years, has decreased by 22 per cent. Disregarding any part of this decrease which may be due to increase of the mean age at marriage, it would appear that the fertility of married women has decreased by about one-fifth and this decrease is the main cause of the fall in the birth-rate. If the fertility of married women had been identical in 1870-72 and 1904 the legitimate births in the latter year would have numbered 247,285 more than those actually recorded. Broadly speaking, it appears that of the total decrease of the birth-rate since 1870 approximately 70 per cent. may be put down to decreased fertility of married women, about 10 per cent. to the decrease of illegitimacy, and the remaining 20 per cent. to the decrease in the proportion of married women at conceptive ages.

With respect to the waning fertility of married women, the Registrar-General draws attention to the fact that in the year 1904 "the falling birth-rate reached the lowest ebb on record in this country." He further shows that although the fertility of women is higher in the country than in the town districts, nevertheless the birth-rate, based on the number of women living at conceptive ages—i.e., from 15 to 45 years—is falling more rapidly in the former than in the latter districts owing, no doubt, to the continued migration of young women to the towns. In the United Kingdom, as well as in the colonies and in most foreign countries, the birth-rate has shown in recent years a tendency to decline, the only exceptions being Russia and Ceylon, in both of which countries the system of registration seems to be defective. Taking as a criterion the average English birth-rates in the latest decennium, it appears than in no fewer than 12 European countries the birth-rates were above the English average by from 2 to 66 per cent., whilst in four only of the European countries were the birth-rates below that of England. It is worthy of note that the recorded birth-rate of France is below that of England by not less than 25 per cent. and that of Ireland below it by 21 per cent. In France the birth-rate has, with slight fluctuations, steadily fallen from 26·7 per 1000 of the population in the year 1872 to 20·9 in 1904. For the great disparities in the birth-rates in the several countries it is difficult to account, although they would probably admit of explanation if allowance could be made for differences in the age and sex constitution of the populations, especially with regard to the proportion of women of conceptive ages. At present, however, this correction is impracticable. For example, if the birth-rates of England and Ireland calculated in the usual way be compared the Irish birth-rate will appear considerably lower than that of England, whereas if the rates are measured by the proportion of legitimate births to the number of married women aged from 15 to 45 years the Irish rate is shown to be considerably the greater. From Sir WILLIAM DUNBAR'S remarks we gather that whilst in his judgment it would be advantageous that the English birth registers should be improved upon the lines adopted by those countries that are more advanced than our own in matters statistical and that they should include additional particulars as regards the age of parents and the number of children born, nevertheless it would be impracticable to adopt for this country the foreign system, say of France, unless our present registration law were entirely recast. Therefore he thinks that it would be unwise at present to disturb the existing system of birth registration in England but considers that a well-devised system of early notification of births—legalised and worked in conjunction with the present registration system on the one hand and with sanitary administration on the other—might prove practicable and useful.

The law of interdependence is recognised by statisticians as applying to the ratios of birth and death in a population. And respecting this the Registrar-General emphasises some elementary facts which are as yet but imperfectly apprehended. He points out that the community is made up of groups of persons who are subject to widely differing rates of mortality. Thus, the mortality of infants in their first year of life is nearly ten times as great as that of persons at all ages, in the second year of life it is about three times, and in the third year it nearly approaches that standard. At ages above three years the mortality falls below the general rate and rapidly decreases until between ten and 15 years it scarcely exceeds one-tenth part of that rate. The mortality then rises, slowly at first and then rapidly, until the fifty-fifth year of age, and then the rise is rapid up to the highest ages. From this it follows that an increase in the proportion of children under three years of age, or of persons above 50 years of age in a community must involve a rise in the general death-rate, and this irrespectively of other conditions of environment. The converse of this is obviously true also. The first result of a decreased birth-rate will be a fall in the death-rate. After three years, however, this fall will receive a check, because of a falling off in the proportion of children with low death-rates. Whatever may be the cause of the increasing decline in the birth-rate there is no doubt that very much may be done to stay the terrible waste of life which the report shows to be still going on in our midst. "This," says the Registrar-General, "should be regarded as one of the master keys of the situation." Again, he remarks, "When it is realised that children who have not reached the fifth anniversary of their birth contribute nearly one-third part to the death roll at all ages, although they form only one-ninth part of the total population, the necessity becomes urgent for a careful consideration of the causes that regulate life and death in this important section of the community." The causes at work in producing what the Registrar-General properly designates 'the enormous death roll due to infant mortality" are fully dealt with in another section of the present report, to which we propose to refer on a future occasion. In his final remarks Sir WILLIAM DUNBAR expresses his personal indebtedness to members of the medical profession throughout the country for the willing and valuable assistance which they have rendered to Dr. TATHAM and himself in their endeavours to record accurate vital statistics and to draw from them legitimate deductions.

The Cambridge Water-supply and Fulbourn Asylum.

THE water-supply of Cambridge is obtained by pumping from two sets of wells to the east of the town, near Cherry Hinton and Fulbourn respectively. At Cherry Hinton part of the water thus obtained is derived from the lower greensand, a stratum which is covered by about 125 feet of impervious gault clay and is effectually guarded from any risk of surface pollution. The rest of the Cherry Hinton supply, however, and practically the whole of the Fulbourn well water are derived from a large area of chalk north of the Gog Magog Hills. The surface of this area is covered only by a few feet of top soil; the chalk in question is a thick stratum of "lower chalk"—compact in its character, traversed by numerous and extensive fissures, and containing bands of stone and clay, which cause water to be held up locally. Some three years ago the Local Government Board drew attention to the possibility of risk to the Cambridge wells as a result of the irrigation of untreated sewage from the Fulbourn Asylum over the surface of land situated on the chalk area from which the Cambridge wells apparently drew their supply. In consequence, representations on the matter were made by the Commissioners of Lunacy to the visiting committee of the asylum. The latter authority, however, did not admit that danger arose, the commissioners were not in a legal position to exert effective pressure in the matter, and the subject dropped. Fortunately, evidence that pollution of the Cambridge supply in this way, if it occurs, has produced water-borne disease in Cambridge has been absent and it may be noted that numerous clinical and biological tests applied to the waterworks company's water at Cambridge have hitherto given no occasion for suspicion as to the character of the water. The question at issue, however, has now been placed on a different footing in consequence of detailed inquiries and experiments conducted by Dr. S. MONCKTON COPEMAN for the Local Government Board, from which we are bound to conclude that a definite risk exists which it would be unwise to disregard or to attempt to minimise.

Fulbourn Asylum has a population of about 615 persons. The sewage of the establishment, some 70,000 gallons daily, runs over surface channels in fields adjoining the asylum and there rapidly soaks into the ground. The upper layers of soil, as Dr. COPEMAN shows, have in all probability become thoroughly permeated and the liquid finds no difficulty in escaping along the fissured layers of the underlying chalk. A good illustration of this was found at a hole made on one of the irrigation areas, roughly six and a half feet deep and of about 450 gallons capacity. When water was run into this hole from a fire-hose the hole did not become full until over 5000 gallons had been discharged into it and this quantity would probably have been exceeded if it had not been for blocking occasioned by washing in of sewage material. At another point Dr. COPEMAN found that an old cesspool, lately taken into use in order to receive sewage from the medical superintendent's house, had an overflow into a swallow hole in the chalk which at once absorbed about 12,000 gallons discharged into it by the hose. Other opportunities of subsoil pollution arise in connexion with defective and leaky drains at the asylum. Works of re-drainage were begun in December, 1904, and have since been carried out in sections. Dr. COPEMAN and the architect of the asylum are agreed in doubting the sufficiency of the scheme for these works which has been authorised by the visiting committee, though they regard it as a decided improvement on the previous order of things. Before these works were undertaken one of the main drains was tested by blocking the outlet and pumping in water continuously at full pressure. No head of water could be obtained in the drain, the water escaping into the soil as rapidly as it was pumped in. The geological conditions in the neighbourhood of the asylum make it probable that polluting matters thus reaching fissures in the lower chalk would be carried to a large basin of underground water held up by comparatively impervious marl at the base of the chalk which in turn rests upon the impervious gault clay. There are various natural overflows to this basin in the form of springs at Nine Wells, at Fulbourn, and elsewhere along the edge of the basin, while the same mass of water is drawn upon by the Fulbourn wells of the Cambridge Water Company, about three-quarters of a mile from the asylum, and by the asylum well itself. The enormous volume of water concerned naturally suggests the question whether access of even a considerable quantity of polluting matter from the asylum can, after all, be regarded as of much consequence and whether, notwithstanding the known ability of particulate matters to travel long distances through fissured strata, the asylum sewage need be considered from a practical point of view as a material risk to the Cambridge supply. Dr. COPEMAN has furnished answers to these questions by two interesting sets of experiments. On July 20th he discharged into a pit on the asylum irrigation area a solution containing 500 grammes each of fluorescin and sodium hydrate, and followed this up by a flush of water from the fire hydrant Numerous samples were taken at frequent intervals from observation stations established at different springs in the neighbourhood, at the asylum well, and at the Cambridge waterworks well at Fulbourn. On the following day distinct fluorescence was observed at "stations Nos. 4 and 5," the latter being a ditch of spring water some two-thirds of a mile north-east of the asylum, while later there appears to have been evidence of fluorescence in the water of the asylum baths. The second series of experiments was made with a larger quantity of fluorescin, five pounds of which were discharged at the same spot on Oct. 18th. At different intervals between Oct. 18th and 27th fluorescence was detected at no fewer than seven widely separated stations. The asylum well was affected four days after the fluorescin was put in and the Cambridge waterworks well at Fulbourn five days later. Dr. COPEMAN is careful not to claim that carriage of bacteria would necessarily correspond with carriage of a dissolved substance but there is no mistaking the significance of the experiment.

It is probable, moreover, that Dr. COPEMAN'S inquiries furnish a key to a puzzling incidence of enteric fever on the inhabitants of Fulbourn Asylum during 1905. After a series of somewhat anomalous cases in March the patients and the staff continued to be attacked by enteric fever week after week during April, June, and July. The total of attacks by this disease during this period was 68 and 16 deaths occurred. Local inquiry was made on behalf of the visiting committee by Dr. B. ANNINGSON and Professor G. SIMS WOODHEAD who issued a report on the subject dated July 25th. This report drew attention to opportunities of infection from person to person, particularly in connexion with the later cases, and also to possible contamination of the milk-supply as the cause of the initial cases. There were, however, many gaps in the evidence tending to implicate milk as the cause of the outbreak and in view of the experimental data since obtained it would seem at least likely that the continuance of the outbreak was due to typhoid matter escaping from the asylum drains or from the asylum sewage irrigation areas into fissures in the chalk and thence being drawn into the asylum well. It is instructive to note in this connexion that part of the work of taking up and relaying the drains of the asylum, to which reference has been made above, had been begun shortly before the commencement of the outbreak. In view of the facts brought out by Dr. COPEMAN'S investigation and of the new considerations regarding the origin of the outbreak of enteric fever in Fulbourn Asylum, to which his report gives rise, new and stringent precautions in connexion with the Cambridge waterworks must be recognised as a matter of necessity. *Means should be found to secure that the* requisite steps are at once taken by the visiting committee of the asylum, the Waterworks Company, and others concerned.

Annotations.

"Ne quid nimis."

THE PHYSICAL STATE OF SCHOOL CHILDREN THE QUESTION OF MEDICAL INSPECTION.

IT will be remembered that a deputation was recently received by Mr. Birrell, the Minister of Education, consisting of delegates from the National League for Physical Education and Improvement. The deputation was headed by the Bishop of Ripon, who appealed on behalf of the league for such inspection of school children as would afford a substantial basis of facts necessary for the formation of public opinion, and undoubtedly it is to public opinion that we must look for a practical method of dealing with a most difficult problem. The result of the recent General Election makes it necessary that the people of this country should trust one another much more readily than they have done. The Liberal must not regard the Conservative as a rabid reactionary, and the Conservative must not think of the Socialist as a *sans culotte* And similarly the ratepayer must not consider every payment out of the rates as spoliation, nor must those so lowly placed as to avoid direct taxation be blind to the burden that is placed upon other shoulders. We must as a nation believe that on the whole we wish each other well, and in particular in the many educational problems now under discussion is this spirit of mutual confidence sorely needed. We do not know what shape the Bill for feeding destitute children may ultimately take but it is clear that this question and the question of the feeding of school children are intimately bound up with the objects which the National League for Physical Education and Improvement has at heart. A method of universal and systematic inspection of school children, such as that which the league suggests, should include the annual record of the height, weight, and chest girth of every child, and would naturally be concerned in the feeding and also in the proper clothing of that child. At once the medical side of such inspection becomes apparent. The contention that a child who has had no breakfast is not in a fit position to be taught whereas a child who has no boots is not rendered the less receptive a pupil by his poverty is wrong, because the absence of boots may cause the presence of disease and the sick child cannot be satisfactorily taught. Medical men will see this point at once, but laymen appear to have difficulty in appreciating it. On Easter Monday there appeared in the *Times* a letter from Professor Howard Marsh, urging the oft-recommended compulsory medical inspection of schools; and undoubtedly it is medical opinion that is required upon all these matters. Professor Howard Marsh spoke of the great benefits that would accrue to the community by the early detection of the common infectious diseases, apart from which medical assistance might well be used in determining such points as the unsuitability of food or clothing. The medical man can say how far the apparently unsuitable breakfast is nutritious and how far the child is really suffering from want of food or want of adequate clothes, while he is taking steps for the prevention of infection from diseases which lay a terrible toll upon our infant population. In regard to the possible reluctance of the public to submit to compulsory medical inspection Professor Howard Marsh says:—

> What view is a parent likely to take when he has had a little personal experience, with which any day may furnish him? Suppose he has three or four children, one of whom being five years old must, according to law, be sent to school There this child catches scarlet fever, and bringing it home gives it to the rest. One dies and two are seriously damaged Further, this parent learns that many of his neighbours' families have also been attacked and that there have been several fatal cases Will not anyone in such circumstances, if he is possessed of ordinary intelligence, hold that as he is compelled by law to send his child to school every possible care ought to be taken to exclude infection? In other words, will he not demand rather than resent inspection?

Professor Marsh would answer his question in the affirmative, and we do the same. Public opinion needs much education in respect of medical service, and the measure of the spread of infectious disease which is definitely due to compulsory school attendance is somewhat under dispute. It is difficult also to persuade the public that medical men are more useful for the prevention of disease than for the cure of disease, yet it is to this end that all scientific efforts are being directed But we medical men must hope and believe that the public will learn to view medical service in a more enlightened way, while we have a right to ask that the public should credit us with having the general welfare at heart and should resent the frequent attacks made upon the probity of the medical profession by ignorant agitators, by cranks, by quacks, and by unscrupulous journalism. Any support given by the medical profession to a movement for the compulsory medical inspection of school children will inevitably be regarded as purely selfish by persons who do not know, or do not think, or are incapable of imagining any motive save self-interest. But we may hope that the public, as a whole, will see, firstly, that such a course would tend to a vast improvement in our national vital statistics; and, secondly, that the prevention and elimination of disease is hardly a self-interested programme for a profession primarily, at any rate as yet, designed for the cure of disease and relying for its income upon its therapeutic rather than its preventive efforts.

THE HYGIENE OF THE LONDON STREETS AND MOTOR TRAFFIC.

IN an annotation in THE LANCET of July 22nd, 1905, p. 233, under the above heading we pointed out that with the introduction of motor traffic in the streets the old pollution—that of the excreta and emanations of horses—would sooner or later give way to the new pollution, the products of perfect and imperfect combustion of the petrol of the motor. Our anticipation has been speedily realised. The new pollution has become unpleasantly evident in those thoroughfares which are now crowded with motor omnibuses. At times the trail of motor omnibuses is nauseating with smoke and petrol fumes. In a letter printed in the *Times* on Wednesday last Mr. Sidney Colvin enters a vigorous protest against this intolerable nuisance—a protest which is endorsed in strong terms in a leading article in the same journal. We earnestly hope that the matter will not be allowed to rest and that a remedy for this intolerable state of things will be imposed on all the owners of vehicles which create such a sickening and completely unwarranted offence. As the *Times* says, "the stink is already chronic and almost universal," and so also we may add is the distracting noise which is made by so many of the motor omnibuses. We believe, however, that the Commissioner of Police for the Metropolis has issued a notice to proprietors of motor vehicles, which requires, amongst other things, that no undue noise or vibration should be caused by the machinery of the motor. No motor vehicles, in our opinion, should be allowed to use the streets until they are proved to do their work without smoke and smell and with the least possible noise. There can be little doubt that motor engineers would speedily find a remedy if only such a regulation were put into force. Meanwhile it is satisfactory to learn that electric motor omnibuses, which are inoffensive as regards both smell and noise, have been run with success.

ANTHRACOSIS OF THE LIVER.

ANTHRACOSIS of the liver, or pigmentation by particles of carbon similar to those found in the lungs and bronchial glands of dwellers in towns, is of sufficient rarity to warrant notice, especially as its occurrence offers a pathological problem of some interest for discussion. A few cases are on record, one of the most interesting being that described by Welch in which there was marked increase of the connective tissue wherever the pigment was found. For this reason Welch gave the name of cirrhosis hepatis anthracotica to the condition. The cirrhosis in this case was, however, probably due to some concomitant toxic substance or irritant other than the carbon particles themselves, since in most cases of anthracosis this overgrowth of connective tissue is wanting. Dr. H. R. Alburger records a case in the Proceedings of the Pathological Society of Philadelphia for 1905, p. 137, with a careful description of the condition and a discussion of its pathogenesis. The patient was a woman, aged 55 years, who was admitted to the Philadelphia Hospital for inoperable carcinoma of the uterus, a diagnosis confirmed by the necropsy, at which the growth was found to have extended to the uterine appendages and the retroperitoneal lymphatics. The liver, which weighed 1400 grammes, extended four fingers' breadth below the costal margin owing to prolongation and flattening of the right lobe from tight lacing. There was a shallow transverse groove across this prolongation with a local thickening of Glisson's capsule. On section the liver presented a red surface with indistinct markings. On microscopical examination the interlobular tissue was found to be thickened and the thickening proved to be due to connective tissue of young growing type. In the new tissue of this character around the blood-vessels there were accumulations of black carbon granules of irregular size and shape which were identical in every particular with those usually found in the lungs and bronchial glands. With high magnification the distribution of the pigment was noticed to be much more general than was apparent under the lower powers; it was found in all parts of the lobule, even about the central vein, and also within the protoplasm of the endothelial cells of the capillary walls. A marked excess of polymorphonuclear leucocytes was also noticed both in the interlobular connective tissue, where most of the carbon was found, and also in the intralobular capillaries generally. The conditions observed within the thorax were extensive pleural adhesions, with old calcareous nodules in both lungs and some recent caseous tuberculous lesions. Unfortunately no note was made of the condition of the bronchial lymphatic glands but there was a moderate amount of anthracosis of the lungs. The other lesions found were chronic interstitial nephritis with severe amyloid change. The spleen was also waxy and showed a small amount of carbon pigment about some of the larger vessels. Dr. Alburger, in his discussion of the channel by which the carbon particles reach the liver, points out that under normal conditions the bronchial glands act as completely effective filters but quotes Weigert's observations as showing that when destructive processes occur in them or they are involved in inflammatory adhesions the conditions are favourable for the escape of the pigment contained in them into the general circulation. On this explanation it might be expected that the pigment would be deposited in various organs; this proves to be the case not infrequently in the spleen, more rarely in the liver, and very exceptionally in the kidneys. A second channel which has been suggested as a possible one from the lungs to the liver is by the lymphatics, but the number of lymphatic glands between these organs renders it highly improbable that any pigment would escape. The portal circulation has also been suggested on the supposition that particles of carbon might have been swallowed, but in this case the particles of pigment would be more likely to remain in the intestinal wall or to be carried to the mesenteric lymph glands. The suggestion offered by Weigert and adopted by Dr. Alburger seems much more plausible. Considering the frequency of disease of the bronchial glands it is highly probable that pigmentation of other organs would be found to be more common if systematic microscopical examination were carried out in all cases, since it is exceptional for such a degree of anthracosis to be present as to be visible macroscopically.

THE "HARDENING" EFFECTS OF COLD WATER.

THE "hardening" effects of cold water ablution are not so universally admitted in England now as they were some few years back when the *cold tub* on getting out of bed in the morning was taken as a matter of course by all, young or old, who aspired to health as well as to cleanliness. In Germany, however, cold affusion is apparently still recognised as a prophylactic against many of the ills that human flesh is heir to, especially in winter. According to an article by Regimentsarzt Fischer in *Der Militaerarzt*, No. 16 of 1905, affections of the respiratory organs, of the digestive tube, of the articulations, and of the muscles, all of which, provoked by chills, are very prevalent amongst German soldiers, in spite of the precautionary measures that are sedulously inculcated, can be minimised or even entirely warded off by the judicious employment of cold water. It is well known, he says, that the impression produced upon the body by the sudden application of cold water affusion determines a passing excitation of the vaso-constrictors which is speedily followed by a paralytic phase wherein the blood tends to flow towards the surface. To the initial sensation of cold there succeeds a sensation of heat; this is what is known as reaction. The colder the water the more intense the reaction. The habit of taking a daily plunge into cold water strengthens the vascular functions of the skin and renders it better able to protect the system against chills. In order to establish this hardening process amongst soldiers Regimentsarzt Fischer proposes to instal in every barrack room a caisson of zinc or wood fitted with a discharge pipe. The water could be procured from the general supply when available or else from reservoirs attached to the wall at a suitable height and should be distributed through a perforated nozzle. Every soldier on rising in the morning would proceed to apply a douche to his entire body (with the exception of his head) during three or four seconds and then, having dried himself superficially, would return to his bed and remain there well wrapped up until reaction was established. As a rule this should not take longer than a minute or two, so the duration of the entire process would not encroach inordinately upon the time usually devoted by a soldier to the elaboration of his toilet. An ordinary English shower-bath would apparently answer Regimentsarzt Fischer's requirements d if it were deemed essential that the soldiers' heads ould not be subjected to the hardening process they uld wear waterproof skull caps as some ladies do when a-bathing.

THE PSYCHOLOGY OF THE BARRACKS.[1]

AN Italian contributor writes:—"'*La Caserma, voilà nnemi!*' exclaims many a continental reformer, who thus oceeds to congratulate the Anglo-Saxon civilisation on the munity enjoyed by the young Briton and American from mpulsory military service. Nor is the exclamation con-ned to the 'reformer,' more or less 'professional.' On e testimony of an English lady in Rome whose *salon* was r years frequented by the foreigner of every nationality the e theme that, more than any other, emerged above the um of polyglot conversation was the freedom reserved for er compatriots of making the career of arms a matter of dividual choice. Not that among the said compatriots ere was not an occasional interlocutor who would dwell on e redeeming points of conscription and even venture on the emark that it might one day commend itself to the Anglo-axon world. He was invariably met by the Italian or the renchman, by the German or the Austrian with the assurance hat he had but to go through their experience to coincide ith their view or to modify his own Certainly of late years he continental press, French, Italian, and German, has eemed with publications disclosing the seamy side of arrison life—its troubles, its trials, and worse, inseparable rom enforced subjection to the levelling roller of 'dis-ipline' in uncongenial, often eminently undesirable, con-itions, moral and physical. True, these publications are ostly in the form of fiction but all bear the impress of amiliarity at first-hand with fact, while embodying actual xperiences imprinted on the memory in characters not to e effaced. The latest addition to the series is of Italian uthorship and though its tone and its tenor are those of the apologia' it supplies us in its very enumeration of the vils that it seeks to minimise with an all too intelligible ommentary on that revolt against the system which, long urrowing beneath the surface, cropped up last autumn hrough the Alta Italia in open refusal to answer the call to arms.' The September and October of 1905 will ong be memorable for the 'cospirazione nell' esercito' which led to numerous arrests and to the subsequent impounding of documents which showed that the 'conspiracy' was international in origin and that the shock of insubordination felt but for a moment in the French garrisons had a yet more pronounced ricochet in those of Italy. Captain Sangiacomo, whose brightly written and thoroughly well-informed *opuscule* seems to have been designed as a corrective to the 'anti-militarist' leaflets steadily, if stealthily, distributed among Italian conscripts, draws with much power a reassuring picture of his country's army. He points with undeniable force to its educative influence, to the salutary effects wrought on the backward proletariat of the towns and the still more backward youth of the rural districts. He is eloquent on the transformation of the city arab and the rural bumpkin, unlettered, untidy, in every sense uncivilised, into the recruit whom a few months of garrison life have taught to read and to write, to be cleanly in his habits, to become proficient in this or that *métier*, so as to rejoin society an efficient and a law-abiding member, not without the much desiderated 'sense of citizenship' Equally eloquent and not less convincing is he when he shows that besides being an educational institution on a national scale the army, reinforced by periodical levies, has been, and still is, a 'unifying influence,' making the Sicilian after a sojourn in Piedmontese barracks, or a Venetian after living in a Calabrian garrison town, more thoroughly Italian in sentiment and in sympathy than he had any chance of becoming if left within the provincial, not to say parochial, limits of his birthplace. From the Alps to Etna, Italy has undergone, thanks to her army, a process of interpenetration, moral and intellectual, of which she is now reaping the fruits, so that even in the matter of spoken dialect a Lombard regiment no longer requires an interpreter when landing in Naples or a Neapolitan when quartered in Genoa. All this, and much more, in favour of her compulsory military service may truly be claimed by Italy. But there is another side to the picture which all Captain Sangiacomo's adroit and genial special pleading cannot annul. Some features of this 'reverse view' are, no doubt, temporary—for example, the defective construction and appointments of the barracks themselves, often old monasteries, with all their insanitary conditions and gloomy 'accommodation' hastily utilised for regimental life and not yet replaced by buildings specially adapted for such a purpose. It is the permanent and far more prejudicial features of 'life in quarters'—features common to every continental army but seen at their worst in Italy—that the latest apologist of conscription cannot put out of sight. In the first place the steady withdrawal from the country to the towns of such masses of young Italians not only encourages, but actually causes, that distaste for rural life and rural labour which, a progressive evil throughout Europe, is peculiarly felt in Italy, whose chief industry is agriculture and whose impressionable youth is beyond all others responsive to the seductive stimulants of urban example. Then again, the absence of all influences or attractions antagonistic to animal indulgence is a feature of Italian barrack life, even more fatally pronounced than is that of other continental countries. Here, indeed, Captain Sangiacomo for once drops the *rôle* of apologist and draws a picture of the moral 'sink' into which the beardless conscript from the country is plunged on his transport to the city garrison which preludes an appeal to the supreme military authority for immediate countervailing measures. I cannot follow him in his enumeration of these deteriorating conditions, beginning with the low 'boozing-ken' and ending with the 'lurido angiporto dove amore e lue venerea sono sinonimi.' Suffice it to say, that the vitiated, often hopelessly septic, constitution with which the Italian conscript rejoins civilian society is a recognised cause of the enfeebled physique which he transmits to his progeny and which, as a Nemesis, explains the increasing rejections of recruits on each successive levy, for 'gracilità' and other bodily disqualifications culminating in the 'epileptoid subjects' whose admission into the ranks is the occasion (*teste* Lombroso) of the abnormal frequency of homicidal mania in the army of Italy. To begin from where I set out, in spite of its latest and not least effective apologist, conscription, as practised and experienced abroad, seems unlikely to conciliate the lasting favour of the countries in which it prevails or to lessen the envy which they undeniably entertain for that sister civilisation which has found the voluntary system of service compatible with the most perfect means of 'national defence' not only in keeping its shores inviolate but in protecting the frontiers of a 'colonial expansion' unequalled in the history of the world."

ANTHROPOLOGY AT OXFORD.

THE University of Oxford established a diploma in anthropology by statute in 1905 and courses of instruction for the same were arranged to begin in Hilary term of this year. The first annual examination will be held in the coming Trinity term. The diploma will "be granted to all persons, whether members of the University or not, who, after pursuing an approved course of study, satisfy examiners, appointed by the University, as to their proficiency in anthropology." Materials for the study of anthropology became available at the time of the acquisition in 1685 of the Tradescant collection which was for a long time the only attempt to make possible the comparative study of human handiwork. Now, however, owing to the collection of human crania established in the department of comparative anatomy by the late Professor Rolleston, the Pitt Rivers collection, and the generosity of the late Mr. C. D. Fortnum, there is ample material for the study of anthropology. Regulations and other information concerning the examination for the diploma and admission thereto may be obtained from the secretary to the committee for anthropology, Mr. J. L. Myres, M.A., Christ Church, Oxford. And here we may fitly refer to the loss which Oxford in particular and science in general has sustained by the death of Professor W. F. R. Weldon, F.R.S., the Linacre professor of comparative anatomy, who died suddenly in London on Good Friday, April 13th. He was an *ex-officio* member of the committee on anthropology and although he ended his days as holder of a post in the University of Oxford, was a Cambridge man, obtaining a Fellowship at St. John's College of that University in 1884. Thence he went to University College, London, as professor of comparative anatomy and zoology and in 1899 he resigned this chair to take up the one at Oxford which he held till his death. We are glad that Oxford has decided to institute an examination in anthropology and venture strongly to recommend a study of this subject to all who have to do officially with races of an alien culture—such as colonial administrators, missionaries, and Government explorers. Much heart-burning, loss of life, and even political complications might have been avoided if explorers and missionaries had not in former years, if not so much nowadays, gone out to alien lands with a fixed idea that "manners they have none and their customs are beastly."

THE SOUTHBOROUGH ISOLATION HOSPITAL.

The vaunted supremacy of English sanitary administration receives at times such shocks that we are inclined to raise the question whether the reputation which we enjoy is really merited, and the story of the action, or rather culpable inaction, of the Southborough urban district council with reference to its fever hospital seems to suggest that in certain matters we are still in the eighteenth century. Through the courtesy of the editor of the *Tunbridge Wells Advertiser* we have received a detailed account of a case which was recently brought before his honour Judge Emden at the Tunbridge Wells county court in which the Southborough urban district council sought to recover from the parents of two patients who had been inmates of its fever hospital the cost of such patients' maintenance, the payment being contested in order to make public certain allegations which, if true, must leave the district council in a most uncomfortable position with those who have reposed trust in it. According to the evidence, this hospital, which contains 12 beds, was to a large extent as a matter of practice, whatever may be the nominal position, under the general supervision of the sanitary inspector, who has, it may be added, no qualification in sanitary matters but who, according to his own showing, is responsible for the payment of a proper and efficient staff. At the hospital there reside a man and his wife, the latter acting as nurse and caretaker and being also responsible for the washing and other work in connexion with the institution. Under her there is a kitchen-maid. It was in these circumstances that the two patients referred to, an adult brother and sister, were admitted as private patients at a charge of one guinea per week each and under the care of the medical attendant to the hospital. So far as the balance of evidence goes, the female patient, although seriously ill, was not fed in a proper or regular fashion, especially at night, and the attendant caretaker, although she had acted as an assistant nurse in charge of a ward at a provincial hospital, did not appear to possess the necessary knowledge for dealing with the case in a satisfactory fashion. Amongst other things, she allowed the patient to get up from her bed when she was unfitted to do so. At night the caretaker went to bed in the ward in which was the patient, giving the latter a stick wherewith to wake her if necessary. On the patient feeling faint there was difficulty in waking the nurse and even then, there being nothing in the shape of stimulants in the hospital, water was the only restorative available! "There was no stimulant in the hospital by the regulations of the council." After this the kitchen-maid was compelled to sit up with the patient for two nights, although she (the kitchen-maid) was altogether unfitted for such a responsible task. It was only after the lapse of four days that a trained nurse was procured from Dover, but her advent seems to have led to so much unpleasantness that pressure is alleged to have been put upon her to prevent her from giving evidence before the court, a circumstance which elicited from the judge some very uncomplimentary criticism. We must confess that the facts brought out during this action manifest a very unsatisfactory condition of affairs at the Southborough hospital—a general muddle is perhaps the fairest comment—and we are by no means surprised to find that the action was dismissed, with costs on the higher scale. We are fully conscious of the difficulty of administering small isolation hospitals but there is no excuse for leaving patients seriously ill in charge of kitchen-maids or for devolving the practical supervision of the institution upon a sanitary inspector, whether qualified or not qualified. Nor can much check on the administration of the hospital be expected from the visit of a district councillor who does not regard it as necessary to enter the hospital. The medical attendant to the hospital is to be congratulated on his evidence, which was eminently fair, notwithstanding the fact that it did not redound to the credit of the Southborough district council.

THE INDUCTION OF LABOUR BY HYPNOTISM.

At a meeting of the Society of Hypnology and Psychology in Paris Dr. Bonjour read some very interesting observations, which will be found in the letter from our Paris correspondent on p. 1143, on the induction of labour by means of hypnotic suggestion. In a certain number of cases under his care he found it possible, by placing the patient in a hypnotised state, to insure the occurrence of labour on a certain date. He had found that this could be done provided that the day was not earlier than eight days before that which had been determined by calculation and examination of the patient as the expected day of the confinement. He further claimed that even if the physician could not be sure of determining the onset of labour on a definite date, yet he could insure that it should commence on a given night, so that the period of dilatation and expulsion would take place the following day. It is difficult to believe that even under the influence of hypnotic suggestion the onset of labour with any certainty can be determined for a certain time or date. We need hardly point out what a gain the possession of such a power would be to the busy medical man. One of the main drawbacks of a large maternity practice is the fact that the exact time at which a given confinement will commence can never be settled with anything approaching accuracy. No doubt mental emotion plays some part in causing the onset of labour, but we are quite ignorant as to what is the part played by the patient's will in this matter. We are still in the dark [illegible] the exact [illegible]f the occurrence of bour at a given time, but in view of the importance at must be attributed to the occurrence of complete aturity of the fœtus and placenta when labour does cur it is difficult to imagine that mere hypnotic influ-ce could bring it on in a case in which it was t very imminent. Indeed, Dr. Bonjour admits that his ethod of suggestion fails if it is attempted more than eight ys before the expected date of the confinement. The use hypnotic suggestion is no new matter in connexion with stetric medicine. A large number of cases have now been aced on record in which hypnotism has been employed to nul or, at any rate, to diminish the pains of labour, and many instances with surprisingly good effect. In one ries of 28 cases published by a Russian observer in no less an 20 as the result of the hypnotic suggestion the labours ok place painlessly, in three the first stage was painless, ile five of the patients could not be hypnotised. In ten stances the hypnotic *séances* were commenced one and a lf months before full term, and in the remaining 18 mediately before the onset of the pains. Sugges-on has been used not only with success in the treatment of the pains of labour but also as a means of eating some of the neuroses of pregnancy. Thus it s proved often successful in cases of nervous vomiting. o bad results have been observed either in the mother the child and it has been found in cases where it is ifficult to induce the hypnotic state on account of the resence of uterine pains the administration of a little loroform is frequently followed by success. The occur-nce of painless, or almost painless, labour during the ypnotic state is a well-authenticated fact and has been served by many trustworthy observers and as a therapeutic easure has undoubtedly proved of considerable value in the ands of many practitioners. We shall await with interest rther evidence as to the possibility of determining the set of labour by the same means but we fear, even if it be roved possible, that the number of cases in which it can be ractised with any degree of certainty will be very small deed.

AN INSULT TO THE PROFESSION.

It has happened more than once in the history of human chievement that the work of some great artist has not lly come home to the minds of his contemporaries and has nly been completely appreciated, even by a later genera-ion, when light has been thrown upon it by the mind of ome supremely gifted commentator. In the twentieth entury things move more quickly than of yore and good ortune brings us the commentator within a comparatively hort period after the work of the artist has been com-leted. We are moved to these reflections by the perusal f a speech recently delivered in the House of Commons by Mr. Henry Vivian, M.P., who at the last election attained he eminence of "Labour Member" for Birkenhead and who eels himself to be acquainted intimately with the views and houghts of the medical profession. His discourse has eminded us of the great painting by Mr. Fildes, R.A., which few years ago charmed all spectators at the exhibition and hich since, in the form of an engraving, has become an rnament of many homes. The picture represented a edical man, apparently a hard-worked country doctor, ending in profound anxiety over the bed of a sick child, mid the humble surroundings of a cottage. To the uperficial view of the ordinary spectator the strong and ugged, though kindly, face was expressive of deep solicitude or the recovery of the little patient and of profound ympathy for the distress of which the illness was the ause, all of which was sufficiently indicated in the bearing nd positions of the parents. The ordinary spectator was quite wrong. Mr. Vivian knows better and has told Parliament all about it. The question which really tro the thoughtful doctor in these situations is to determ whether it would be more profitable to him to cure th child and to take his chance of eventual payment from the father, or to withhold his hand and thus to secure the secret commission which he would receive from the coffin maker. We had never before thought of this aspect of the question, and we recognise at a glance the illuminating power of genius—the genius of misrepresentation.

HEIGHT AND BODY-WEIGHT.

According to the formula propounded by Paul Broca a grown man's weight in kilogrammes should correspond with the number of centimetres in his stature above one metre. In order to test the approximate accuracy of this statement Generalarzt Villaret of the German army has collated data from the records of 42,563 soldiers who had all been accepted as physically fit for the service. As far as regards little men—that is, men whose height varied between 1·54 and 1·59 metres—the formula of Broca was confirmed, but with medium-sized men—that is, men whose height varied between 1·60 and 1·74 metres—the body-weight was under the standard, the divergence increasing with almost mathematical regularity from below upwards. In the case of tall men—that is, men above 1·74 metres (5 feet 7 inches)—the divergence was still greater and here, too, it increased regularly in accordance with the individual's height. Generally speaking, Generalarzt Villaret found that a recruit's weight after a few months' service was largely influenced by his calling before enlistment. Men coming from a sedentary occupation, such as clerks, tailors, saddlers, and so on, put on weight very quickly, whereas those who had had opportunities for over-feeding, such as confectioners, bakers, butchers, and brewers, lost it with corresponding rapidity. Recruits recovering from serious illnesses, or who had had to work under defective sanitary conditions, might safely be accepted when below the standard, for their weight was certain to increase, and the same rule applied to youths brought up in poverty who had never in their lives had as much food as they could eat.

THE VERMIFORM APPENDIX.

In a memoir published several years ago Dr. J. A. Berry gave a detailed account of the histology of the true cæcal apex or the vermiform appendix in animals from pisces to anthropoids. In a paper read at the first International Federation Congress of Anatomy held at Geneva in August, 1905, and reproduced in the *Journal of Anatomy and Physiology*, vol. xl., part 3, p. 247, Dr. Berry, in conjunction with Dr. L. A. H. Lack, gives the results of his later researches in man, influenced in their direction by the important essay of Mr. C. B. Lockwood on Appendicitis, its Pathology and Surgery. Dr. Berry having in his first paper shown that lymphoid tissue is the characteristic feature of the appendix, in his present communication, aided by Dr. Lack, gives the results of his investigations as to the age at which lymphoid tissue first appears in the human appendix, for it does not exist in the newly born infant; next the age at which it tends, if at all, to disappear; and, lastly, discusses the question whether the obliteration of the human appendix is a physiological or a pathological process. In regard to the first point, whilst at birth there is practically no lymphoid tissue and lymph follicles are absent, within 14 days two well-marked lymph follicles have made their appearance and lymphoid tissue is scattered profusely throughout the whole of the mucosa. At six weeks there are from eight to 12 lymph follicles, and the whole of the mucosa and submucosa, as is clearly shown in the reproduction of a photograph, is with lymphoid tissue. At 32 weeks the r of man is to all appearances an actively There are, then, to be met with in the e section from ten to 12 well-marked licles and about 160 tubular glands. drawn in regard to the first point is, whilst there is no lymphoid tissue in the cæcal apex of the lower animals or in the appendix of man at the time of birth the portion of gut under consideration has become within a period of from one to six weeks an actively functional lymph gland. In regard to the second point the writers entertain no doubt that the lymphoid tissue does tend to disappear from the human appendix, for the number of lymph follicles visible in transverse sections of appendices will be found to become less numerous with advancing age, so that whilst six or seven follicles may be found in a transverse section of an appendix up to the age of 40 years, at the age of 60 years and above there are only traces or a total absence of them. The lymphoid tissue, however, never totally disappears. Lastly, they consider that obliteration of the vermiform appendix is a pathological process. On these various grounds the vermiform appendix of man may be regarded as by no means a vestigial remnant or an organ in a state of retrogression but as an actively functional lymph gland. The writers consider that the passage of inert foreign bodies into the appendix is extremely rare, though the entrance of living organisms such as the trichocephalus is easily conceivable and has been several times demonstrated in cases where appendicitis was present.

ENTOPTICS.

In a communication made to the Royal Dublin Society in March of the present year Professor W. F. Barrett calls attention to the phenomena of entoptic vision or the self examination of objects within the eye. It is remarkable that the subject of entoptics appears to have dropped out of the consideration of most of the writers of recent ophthalmological manuals and treatises. The reason of this is probably to be found in the circumstance that it belongs properly to physiological optics and is therefore discarded by authors who require all the space at their command for the consideration of the defects, disorders, and diseases of the eye; yet the appearances presented by motes in the eye—muscæ volitantes—are so annoying that inquiries as to their nature and relief are constantly made by patients. In many instances a favourable prognosis may be given with assurance that they will become fainter or less numerous and will ultimately disappear, either by absorption or by rising out of the line of vision; for their apparent descent is attributable to their specific gravity being lower than the surrounding fluid. They hence ascend and their shadow on the retina being inverted they appear by the law of projection to fall. Nevertheless, they may in general be regarded as indicative of some degree of impaired nutrition of the health or of the eye and should not be disregarded by the physician as altogether unimportant. Entoptic phenomena are most easily demonstrated and examined by looking at a clear sky or a well illuminated street through a pinhole aperture in a piece of cardboard or thin metal held close to the eye. Professor Barrett points out that entoptic objects are seen inverted, the reason being that the rays of visible direction proceeding from the aperture do not cross at the nodal point of the eye, and that as the path of the projected shadow of any entoptic object corresponds to the path of the incident rays crossing at the pin aperture only the enlargement of the image is in the direct ratio of the distance of the pinhole from the pupil to its distance from the illuminated screen on which the shadow is projected. He proceeds to show how by a simple calculation the size of a musca can be determined and how it may be delineated. Professor Barrett promises that in a future communication he will describe an instrument which he has devised and which he has termed the entoptoscope by which the position and the size of floating muscæ can be determined.

THE HONOURS TO GUIDO BACCELLI.

The "plebiscito universale di ammirazione" of which on Sunday, April 8th, the head of the Roman Medical School was the object must have more than realised the intentions of its promoters. From Royalty itself to the leading representatives of every interest, professional and lay, there was but one sentiment that animated the distinguished auditory that thronged the Capitol—one of respect, esteem, and kindly "brotherhood" towards the physician, the man of letters, the citizen, and the statesman whom it had met to honour. Not for the first time has The Lancet[1] borne testimony to what Italy and the outside world owe to the clinician and pathologist who has worthily held up the torch transmitted from Baglivi to Morgagni and from Morgagni to the modern schools. We have only to-day to congratulate the "youngest of the Great Powers" on her still possessing a son so able, so accomplished, so public-spirited, so inspiring, whether in the clinical lecture room or in the legislative chamber—possessing him, moreover, in the maturity and the unimpaired vigour of his many-sided energy. The crowning work of his life—the foundation of the "Policlinico"—was the subject of special eulogy on the occasion of April 8th and we may now repeat what we expressed when that great institution was planned—to wit, our sense of the truly catholic spirit in which its founder drew upon the experience of the scientific world for its equipment, among the evidences of which was his selection of the English Lister as the counterpart of the Italian Morgagni, to typify, by the sculptor's art, the genius of surgery side by side with that of medicine.

> "Dum Tibris Etruscum in mare defluat
> Flavente lapsu, stet Polyclinicum
> Fulgens, tributurum salutem
> *Italiae dominaeque Romae.*"

May it continue to stand not only for the humane science it cultivates and reduces to practice but as testimony to the "fratellanza," the brotherhood, that knows no distinctions of race or creed, responsive only to the watchword which makes "*all men's good*, each man's rule."

ANGINAL ATTACKS IN CONGENITAL HEART DISEASE.

It is frequently observed that children with congenital heart disease suffer from convulsions of a greater or less degree of severity but the occurrence of anginal attacks analogous to those of adults is extremely rare. Dr. Norbert Swoboda showed a case of this kind before the pediatric section of the Gesellschaft für innere Medicin und Kinderheilkunde in Vienna on March 1st, which is recorded in the *Wiener Medicinische Wochenschrift*. The patient was an infant, aged 18 months, of weakly, ill-developed appearance. There were marked cyanosis and persistent dyspnœa, the fingers were clubbed, and the extremities were cold and blue. There was marked pulsation in the præcordial region but no thrill. On auscultation a loud systolic murmur was audible over the whole cardiac region, while the pulmonary second sound was accentuated. On examination by the Roentgen rays the cardiac shadow was distinctly enlarged both to the right and the left. The general condition of the child until the age of 14 months was fairly satisfactory, but from that time, either during or immediately preceding the act of defæcation, severe attacks of anginal character developed, lasting from one to 12 hours.

---

[1] The Lancet, Jan. 6th (p. 51) and March 31st (p. 808), 1894.

ks occurred whether the motions were hard or the result of an enema but no local condition ıd to account for them. At the beginning of cks the infant would usually groan and soon ı an extreme degree of expiratory dyspnœa with stress, the eyes starting from their sockets, the oming bluish-black and cold, while eventually con- ss was sometimes lost. The attacks frequently ended niting, epistaxis, or cough. During their course the ecame small, though not accelerated, while the murmur was no longer audible. In the intervals ı the seizures the infant wa cheerful and active but eral condition was much ôpressed by them and a weakness of the left arm eveloped. A somewhat case has been recorded by Heubner in an infant ve and a half months; in th case death occurred in the attacks. Apart from th rarity of the condition voboda's case is of interest om the association of izures with the act of defæcion and also from the uent weakness of the left arm

TOAST.

BABLY modern methods of ming flour have much to ith the lack of flavour whichmarks the present-day of bread. One thing at leaswe know, and that is roller milling, as distinct fn the old method of ling wheat between stones, lea to the elimination of germ of the wheat, and the culiar nutty flavour—h is now unfortunately a atter of history—of old-fashioned loaf was due paps to the retention his germ. The public, or at events a large section it, would appear to be e stupidly ready to ifice genuine dietetic quality invour of colour—bread adays must be quite white andlk must look yellowish nd these silly criteria of an tation excellence are ly supplied. The increasingopularity of toast is omewhat interesting fact in t it possibly indicates t, after all, the public resents, nay be unconsciously, insipidity of modern bread. Toast is not only in nand on the breakfast table butoften appears now in ce of the roll or slice of bre on the dinner table o. This quite common prefer which is exhibited r toast may be because experiehas taught that well-ade toast is more digestible ı bread. It is more obable that toast is popular bee it is palatable and as an attractive flavour. In a sir way the crusty part bread is chosen by a goodny people because it ossesses a flavour analogous in a to that of toast, which s decidedly more interesting to thlate than the soft and oist portions of modern bread, fese are with difficulty ompletely masticated and insaled, being too solid in heir mass to allow o the free incration of the digestive juices. Toast place a lighter ta the digestive functions since during its peparatio so of the starch grains of the flour are rptured whileme are converted into dextrin which is asily soluble. rther, the crispness of toast necessitates its being comtely moistened in the mouth before it c be swallow As a rule, therefore, toast is thor submitted tthe action of the preliminary dig process in thenouth. It is important, however, ast should be crisall through, as otherwise t portions tend to ecome plastic and soft the intead and, like it, dicult of digestion if not like ne masticated. New read is not necessarily thorote. It only proves so in some cases, because on indi of its plasticity and oftness there is a strong ac to swallow it before it is thoroughly masticated nsalivated. If bread posessing the peculiarly ctive flavour which characterised it in the days of e milling were placed on the modern breakfast or dinner table the preference for toast would, we feel safe in saying, very sensibly diminish.

THE STATISTICS OF THE MEDICAL STUDENTS IN GERMANY.

Statistics published by the *Frankfurter Zeitung* as to the number and distribution of medical students throughout the German Universities show in a general way that the popularity of medical studies increased progressively from 1860 to 1890, since which year it has declined. During the winter session 1905–06 the total number of medical students in Germany was 6080; last summer it was 6032; during the previous year 6153. In 1885 the total was 7725; in 1890, 8986; and in 1896, 7851. These figures include foreign students, of which there are at present 895 registered in the Universities; last summer there were 751. German subjects registered as medical students numbered in 1861, 2000; in 1872, 3365; and in 1881, 4389. The proportion per 100,000 inhabitants shown by medical students of German nationality at the present date is 8·5; in 1890 it was 14, in 1881 it was 9·7, in 1872 it was 8·5, and in 1861 it was 5·6. The popularity of medical studies in the different universities is shown as follows. Since 1882 the number of medical students at Berlin, Munich, Freiburg, Heidelberg, Jena, Kiel, Giessen, and Rostock has increased 50 per cent. and at Erlangen over 25 per cent. At Greifswald it has decreased 100 per cent, at Breslau about 50 per cent, at Leipsic and Würzburg more than 25 per cent, and at Königsberg and Halle more than 20 per cent. Münster alone of German Universities has no medical faculty.

A sessional meeting of the Royal Sanitary Institute will be held at the Parkes Museum on Friday, April 27th, at 5 P M, when a discussion on the Consumptive at Home will be opened by Dr. G. A. Heron. Sir R. Douglas Powell, Dr. J. E. Squire, and Dr. F. C. Shrubsall are expected to take part in the discussion, On Saturday, April 28th, a visit will be made by members of the institute to the Mount Vernon Hospital for Consumption at Hampstead. Members will meet at the hospital at 3 P.M, and after the visit will be entertained at tea at Upper Frognal Lodge. Those wishing to attend the visit should send in their names to the secretary by Tuesday next, April 24th.

CREMATION AND SANITATION.

Under the auspices of the Royal Sanitary Institute a provincial sessional meeting was held at Leicester Town Hall on March 24th, when the subject discussed was Cremation. Colonel J. Lane Notter, R A.M.C., chairman of the council of the institute, presided.

The Chairman, in opening the proceedings, said that very decided sanitary advantages were connected with the practice of cremation and it was satisfactory to find that this method of disposing of the dead was growing in favour with all classes.

Dr C Killick Millard (medical officer of health of Leicester) read a paper on Cremation, giving at the same time various particulars relating to the crematorium of the Leicester Corporation. He said that the practice of disposing of the human body by fire was largely adopted by the ancients, and in Greece the right to be burnt was only denied to suicides, young infants, and persons struck by lightning. He then continued as follows:—

General Considerations.

Some people prefer not to face this question because they are over-concerned about the fate of the body after death and fear to suggest any alternative to old-fashioned and familiar custom. Others, again, do not face it because they feel so little concern and do not care what happens to the body. Neither of these extremes, it seems to me, is right It is true that the body after death is no more than the empty shell from which the spirit—the living and immortal soul—has fled, but the body is, nevertheless, sacred in death as well as in life, and it is surely our duty to provide for its reverent disposal by the method which, in the light of modern science and with due consideration for the interests of the living, appears to us to be the best. The human body, in common with bodies of all living things, must inevitably, sooner or later, undergo disintegration and the highly complex organic substances of which it is composed must eventually be resolved into simpler compounds, such as water and carbonic acid, which are dissipated, leaving only a small amount of mineral residue behind. There are in this country only two practicable methods of disposing of the dead—namely, by inhumation or earth burial and by cremation. I hope to be able to show that of the two the latter—cremation—is much to be preferred, as being more sanitary, more scientific, and much less repulsive to sentiment. When the movement in favour of cremation was initiated in England about 30 years ago all sorts of objections were raised against it. It was asserted that cremation would create a nuisance and would encourage crime. It was also described as heathenish, revolting, and opposed to Christian teaching. The Cremation Society of England was formed in 1874, with Sir Henry Thompson as president, and it is undoubtedly due to the enthusiasm and dogged perseverance of the society that the change in public opinion has chiefly been brought about. The crematorium at Woking, the first in this country, was erected in 1879, and was for several years the only one in England. In 1892, however, a second crematorium was opened at Manchester, and this has been quickly followed by many others in various parts of the country, until at the present time there are no less than 13. The crematorium in Leicester was opened in 1902 but only one cremation took place in that year. In the following year there were five cremations, then eight, and last year there were 15. Many of these were from neighbouring towns and almost all were of persons belonging to the upper or middle classes, this being the experience everywhere. As the fashion spreads, however, there is little doubt, I think, that the working classes will also avail themselves of it.

CREMATION ABROAD.

In several foreign countries the movement, begun about the same time as in England, is making equal progress. In Germany cremation was introduced in 1878 and is rapidly increasing; according to statistics recently published there are nine crematoriums and 86 cremation societies, with a membership of more than 22,000. The figures are remarkable inasmuch as cremation is forbidden in several of the German States. In the United States of America there are already no less than 26 crematoriums. In France there are four but the one in Paris is used to a far greater extent than the corresponding one in London. In Switzerland there are four and there are two in Sweden and one in Denmark. Other countries which possess crematoriums are Japan, Canada, and Australia, while one is also to be found at Buenos Ayres and one is being established in Bombay by educated Parsees, who object to the present method of exposing their dead on the Towers of Silence. As regards the number of cremations performed in Paris alone the total amounted to 3147 up to the end of the year 1903, and it has since been considerably increased. In the United States of America no less than 3160 took place in one year (1902). In Germany the number in one year (1903) was 1074. In Great Britain there were 604 during 1905, as compared with 566 in 1904 and 476 in 1903, whilst the total for this country since the commencement of cremation up to the end of 1905 was 5020.

COST OF CREMATION AND LEGAL FORMALITIES TO BE OBSERVED.

Cremation is not necessarily so expensive as some people think. The amount of fuel required to consume the human body completely in the latest form of apparatus is only about half a ton of coke, costing a few shillings, and against the cost of fuel there is a set-off in the land required for the grave. The interest and sinking fund on the capital outlay in building a crematorium and cost of up-keep are serious items at present, whilst the number of cremations is small, but they will diminish greatly as the practice becomes popular.

The fees for cremation at the Leicester Crematorium are £2 2s. for a resident of Leicester and £5 5s. for a non-resident. In the case of a poor person the corporation may, if it thinks fit, remit a portion or the whole of this. In addition to the cost of the actual cremation there are fees for the special medical certificates required by l At present cremation is unfairly handicapped in this resp as no fee is payable for the nominal certificate of de which is all that is required before burial. There is a gr contrast between the stringent precautions insisted up before cremation and the notoriously inadequate precautio with which the law is at present satisfied before buri Briefly, the procedure before cremation under the Act 1902 is as follows:—A statutory declaration has to be mad on a prescribed form before a justice of the peace or com missioner of oaths to the effect that there is no known cau why cremation should not take place. Two medical certi cates have to be obtained also on prescribed forms, o from the ordinary medical attendant of the deceased an the other—the confirmatory medical certificate—from medical man who is of not less than five years' standing an holds some official position specified in the regulations, suc as medical officer of health, certifying factory surge medical referee under the Workmen's Compensation Act, o physician or surgeon to a hospital. The ordinary medical certificate of cause of death has to be given and the deat registered as usual. Lastly, all certificates have to be sub mitted to the medical referee appointed by the cremat authority under the Act and no cremation can take pla until authorised by him. The medical referee has full power to decline to allow a cremation to take place without stating an reason, and in any case where he thinks it desirable he ma require that a post-mortem examination should be made. Although I think that some of the details of this procedur might be simplified with advantage, it is not really so fo midable as it sounds, and when all deaths have to be certified properly the difference in trouble between cremation an burial will be less marked.

THE COMPARATIVE ADVANTAGES OF CREMATION.

Arguments in favour of cremation as compared with inhumation may for convenience be divided into two classes—namely, those which are based (1) on sanitary grounds and (2) on sentimental grounds respectively.

1. The practice of inhumation in crowded graveyards in large towns is essentially insanitary and must be a menace to the health of the surrounding inhabitants. As regards intramural interments the revelations which came to light as the result of an inquiry made into this subject some 50 years ago smote the public with such horror that an Act of Parliament was passed prohibiting this form of interment. Of course where cemeteries are formed at a distance from the towns, out in the open country, as is the case at Leicester, the evil is greatly reduced, but the process of decay and corruption still goes on.

In considering the possible influence of a cemetery upon those living in the vicinity I am able to speak with some personal feeling, as my own residence is in close proximity to the Leicester Cemetery, a narrow strip of only 40 yards separating my garden from the cemetery fence. In this cemetery, the subsoil of which is a stiff clay, some 2000 bodies, representing, perhaps, 200 tons of human remains, are deposited every year. As regards any nuisance arising from the process of cremation I can speak from experience, as nearly 40 cremations have already taken place at the Leicester Corporation crematorium, which is only 300 yards from my house. I have never noticed the slightest nuisance, nor, indeed, from the nature of the apparatus, is any nuisance possible, even if it took place in a crowded neighbourhood. A light puff of smoke when the coffin is first introduced is all that reveals the fact that a cremation is taking place, and even this, I believe, can be overcome.

2. It is sometimes said that popular sentiment is against cremation. No doubt this is so at present, because cremation is new and strange whilst interment is old and familiar; but whoever seriously considers the fate which inevitably befalls the body after it has been placed in its "last resting place" must assuredly admit that apart from prejudice sentiment should be in favour of cremation.

THE DISCUSSION.

Alderman A. E. SAWDAY said that personally he w that Leicester was in the van of progress with reg cremation, as he had come to the conclusion that th undoubtedly the best form of disposing of the dead. So as the question of cost was concerned the fees fixed by corporation of Leicester were the lowest that could pos be arranged without the process becoming a burden o rates.

Dr. P. BOOBBYER, medical officer of health of Nottingham, said that he was personally in favour of cremation but he felt that it had many serious difficulties to face. From the public health standpoint it was admirable but on sentimental and religious grounds, according to the Church of Rome, and on medico legal grounds, it was, in the opinion of some people, open to great objection.

Councillor G. CHITHAM, the chairman of the corporation burials grounds committee, expressed the hope that the result of the conference might prove useful in bringing about a greater interest in cremation.

Alderman GEORGE CLIFTON, speaking as a medical man and one of the oldest members of the Leicester branch of the National Cremation Society, said with regard to the question of sentiment that the spectacle presented by bodies exhumed after having been buried for some weeks or months was calculated to make the beholders hesitate before wishing their friends to be subjected to earth burial.

Dr. WILLIAM COLLINGRIDGE, Alderman WINDLEY (the chairman of the sanitary committee of the corporation of Leicester), Mr. J. E WILLCOX, and Mr. W. A. CLARKE (deputy coroner for the borough of Leicester) also took part in the discussion.

After luncheon the members of the institute visited the borough crematorium.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the General Sanitary Circumstances and Administration of the Rural District of Sleaford, by Dr. L. W. DARRA MAIR [1]—Dr. Mair gives a surprising account of what passes for "local sanitary administration" in Lincolnshire. The Sleaford rural district, with an area of over 200 square miles, has a total population of some 17,000, mainly grouped in numerous villages on the edge of the Lincolnshire *fens*. Certain of these villages possess public water-supplies which have been obtained by deep boring into the great oolite or by impounding natural springs. The majority of the villages, however, are in a very unsatisfactory position with regard to water. Some depend upon surface wells situated in shallow patches of gravel overlying a clay soil and liable to serious pollution; others obtain their water from local streams which are contaminated by sewage. Among the latter is the village of Billinghay, where about 1200 inhabitants are dependent for water on dipping places in Billinghay Skirth, many of which are below the outfalls of the local sewers. Similarly the occupants of groups of dwellings near to the River Witham are obliged to draw their supplies from that stream which has already been seriously polluted in its higher reaches. After making allowance for the fact that in some villages where public water-supplies exist the distributing mains are deficient, and thus only a portion of the village gets the benefit of the supply, Dr. Mair reckons that not more than 20 per cent. of the population of the district is supplied with safe water. If, however, the rural council had been guided by, and had taken action on the advice of, its officers "it is probable that nearly 80 per cent. of the population would be so supplied at the present time." Several feasible schemes for the combined supply of villages have been prepared at different times. The main reason for their having come to nothing is that the rural council has for many years been in the habit of regarding water-supply (as also other sanitary matters) as of purely parochial concern. The council consists of 57 members, who meet at Sleaford workhouse once a month after the conclusion of the Poor-law business. This unwieldy body seldom appoints any committee and appears to be content to dispose of all sanitary questions by referring them to the parish councils of the places concerned. Parish councils have, of course, no responsibility in the matter and where the question of combined action in several parishes arises they not unnaturally fail to agree over more or less trivial points, with the result that the district council is furnished with what it regards as sufficient excuse for doing nothing. In 1896 the surveyor reported on the need for a public water service for the neighbouring villages of Great Hale and Little Hale and suggested two alternative schemes for providing both places with a common supply. The report was "referred to the parish councils." Opposition came from both and one of them reported that a parish meeting had been convened at which it was unanimously resolved "that a cistern be built to contain the water running from the parish church (subject to the approval of the vicar and churchwardens) and the ratepayers consider that would be sufficient to supply the village." Both schemes were then allowed to fall through. Subsequently, the parish council in question was sensible enough to prefer the great oolite to the church roof and obtained an abundant supply by deep boring. But the neighbouring village, less than a mile away, was left without water, although, whilst they were about it, both places could have been supplied almost as easily as one. Dr. Mair gives other and equally striking instances of the inefficiency which has resulted from the district council's method of performing or neglecting its duties. One result of the policy of placing the duty of preparing water schemes upon irresponsible parish councils has been the frequent employment of water diviners, whose advice on several occasions has entailed a large amount of boring without finding water. Besides referring to outbreaks of enteric fever which have occurred from time to time in association with polluted water in this district, Dr. Mair draws attention to the insanitary condition of many of the houses and their surroundings and to serious pollution of streams by sewage. There is no public scavenging, even in the larger villages. The duties of inspector of nuisances are performed by the council's surveyor who has but little time to devote to them. Two road surveyors each receive £40 a year in respect of work as "assistant inspectors of nuisances," which in practice they do not perform.

On Sanitary Circumstances and Administration in the Urban District of Abertillery, by Dr. S. W. WHEATON.[2]—This report describes many unsatisfactory conditions met with in an important and growing mining district in Ebbw Vale. Special difficulties, particularly in the matter of water-supply, are created by subsidence of surface due to removal of the underlying coal. The sources of supply are always liable to alteration and the supply obtained from the main waterworks at Cwmtillery has greatly diminished of late. The springs become tapped and drawn into the mines and even the surface of the tops of the hills becomes traversed by deep fissures, so that surface water also finds its way into the mines and is lost for the purpose of water-supply. From the same cause one of the two storage tanks has become cracked and has had to be put out of use, with the result of further curtailing the water available. The supply is intermittent and in many of the dwellings (which usually have no storage cisterns) water is available only for a few hours daily. Moreover, the water-pipes in the upper part of the district during periods of intermission are constantly being sucked dry as a result of water being drawn off at lower levels, so that there appears to be serious risk of insuction of polluting matters through leaks or open taps. While other sanitary defects, notably the bad condition of many of the dwellings, are also in some degree related to subsidence, much of the insanitary character of Abertillery seems to be attributable to local indifference and faulty administration. Builders, for instance, are allowed to put up dwellings of imperfectly burnt bricks, with mortar crumbling and unpointed, with defective roofs, cracked slates, and so on. Yards are badly paved and drained, the yard gullies being often "surrounded by pools of stinking sewage which percolates into the ground near the dwelling," while Dr. Wheaton directs special attention to the filthy condition of many of the slaughter-houses and bakehouses. There is a daily collection of house refuse from pails and iron bins. Difficulty has arisen in disposing of this refuse and a refuse destructor has been suggested. Dr. Wheaton, however, gives a sound reason against this proposal—namely, that owing to the character of the district and the steepness of the roads it would be impossible to continue the daily collection of refuse if all of it had to be taken to a central depôt for destruction. He also criticises the present practice of employing a local medical practitioner at the small salary of £60 per annum to perform the duties of medical officer of health in a district the population of which has already reached 27,000, and suggests combination of Abertillery with Nantyglo and Blaina, and other adjoining districts of Ebbw Vale, for the purpose of employing a medical officer of health to give his whole time to the work. Desirable combinations of this kind have been freely advocated by Local Government Board inspectors in recent years and it may be hoped that the central authority does not intend to be deterred, here or elsewhere, by mere local opposition from giving effect to the important proposals which have been made by its expert staff in the matter.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8943 births and 5157 deaths were registered during the week ending April 7th. The annual rate of mortality in these towns, which had been equal to 15·8 and 17·0 per 1000 in the two preceding weeks, was again 17·0 during the week under notice. In London the rate fell to 16·8, and was 1·8 below that which prevailed in the previous week, and in the 75 large provincial towns the average rate was 17·0. The lowest death-rates in these towns during the week were 8·4 in Willesden, 8·9 in Aston Manor, and 9·3 in Leyton and King's Norton; the rates in the other towns ranged upwards to 23·8 in Reading, 25·4 in Burnley, 27·1 in Warrington, and 28·1 in Middlesbrough. The 5157 deaths in the 76 towns included 457 which were referred to the principal infectious diseases, against 414 and 492 in the two preceding weeks; of these 177 resulted from measles, 133 from whooping-cough, 49 from diphtheria, 48 from diarrhœa, 31 from scarlet fever, 19 from "fever" (principally enteric), but not one from small-pox. No death from any of these infectious diseases was registered during the week in Bournemouth, Ipswich, Norwich, Stockport, Wigan, York, or in seven other provincial towns; while they caused the highest death-rates in Liverpool, Preston, Walthamstow, Smethwick, and Warrington. The highest rates of mortality from measles occurred in Liverpool, Blackburn, Newcastle-upon-Tyne, Wathamstow, and Hornsey; from whooping-cough in West Bromwich, Smethwick, Handsworth, Plymouth, and Warrington; and from diarrhœa in Rochdale and Smethwick. The mortality from diphtheria, scarlet fever, and enteric fever showed no marked excess in any of the large towns. No death from small-pox was registered during the week either in London or in any of the 75 large provincial towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals, which had been ten and eight at the end of the two preceding weeks, were still eight at the end of the week under notice, no new case having been admitted during the week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday April 7th, was 2322, against numbers declining from 2628 to 2386, on the five preceding Saturdays; 292 new cases were, however, admitted during the week, showing an increase of 69 upon the number of admissions in the previous week. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 320 and 337 in the two previous weeks, declined again to 332, but exceeded the corrected average for the corresponding week in the four years 1902–5 by 27. The causes of 54, or 1·0 per cent., of the deaths registered in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, West Ham, Leicester, Nottingham, Salford, Leeds, Newcastle-upon-Tyne, and in 44 other large towns; while excessive proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, Blackburn, Sheffield, and South Shields.

In 76 of the largest English towns 8055 births and 5200 deaths were registered in the week ending April 14th. The annual rate of mortality in these towns, which had been 17·0 in each of the two preceding weeks, was last week equal to 17·1 per 1000. In London the rate was 17·4, while the average rate in the 75 other large towns did not exceed 17·0. The lowest death-rates in these towns during the week were 8·0 in Willesden, 8·8 in East Ham, 9·2 in Tottenham, and 9·7 in Portsmouth; the rates in the other towns ranged upwards to 22·1 in West Bromwich, 22·6 in Smethwick, 23·1 in Tynemouth, and 25·6 in Liverpool. The 5200 deaths in these 76 towns included 518 which were referred to the principal infectious diseases, against 414, 492, and 457 in the three preceding weeks; of these, 198 resulted from measles, 147 from whooping-cough, 54 from diarrhœa, 51 from diphtheria, [illegible] from scarlet fever, 26 from "fever" (principally enteric), but not one from small-pox. No death from any of these infectious diseases was registered last week in Hastings, Reading, Norwich, Warrington, West Hartlepool, Swansea, or in four other towns; while they caused the highest death-rates in West Bromwich, Manchester, Rotherham, Leyton, Yarmouth, and Liverpool. The highest death-rates from measles during the week occurred in Bury, Manchester, and Liverpool; from whooping-cough in Cardiff, Bournemouth, Leyton, Smethwick, and West Bromwich; and from diarrhœa in Middlesbrough and Tynemouth. Diphtheria caused three deaths in Sheffield, three in Rotherham, and two both in Bradford and Hull. Three deaths were referred to "fever" in Leeds, and two each in Bradford, Newcastle-upon-Tyne, and Rhondda. No death from small-pox was registered during the week either in London or in any of the 75 other large towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals declined to seven at the end of last week, having been eight at the end of each of the two preceding weeks, no new case having been admitted during the past three weeks. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday, April 14th, was 2301, against numbers declining steadily from 2628 to 2322 at the end of the five preceding weeks; 270 new cases were admitted to these hospitals during the week, against 223 and 292 in the two previous weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 320, 337, and 332 in the three preceding weeks, rose during the week under notice to 357 and exceeded the corrected average for the corresponding period in the four preceding years by 61. The causes of 60, or 1·1 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Manchester, Salford, Bradford, Leeds, and Newcastle-upon-Tyne; whereas the causes of 12 deaths in Liverpool, seven in Sheffield, five in Barrow, and four both in Preston and in Hull were not certified.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·0 and 18·9 per 1000 in the two preceding weeks, further rose to 19·4 during the week ending April 7th, and exceeded by 2·4 the mean rate during the same week in the 76 large English towns. The death-rates in the eight Scotch towns ranged from 17·9 and 18·0 in Glasgow and Aberdeen to 22·[illegible] in Greenock, 22·2 in Paisley, and 23·4 in Dundee. The 65[illegible] deaths in these eight towns included 20 which were referred to measles, 15 to diarrhœa, 12 to whooping-cough, two to "fever," one each to scarlet fever and diphtheria, and not one to small-pox In all, 51 deaths resulted from these principal infectious diseases during the week, against 81, 57, and 62 in the three preceding weeks. These 51 deaths were equal to an annual rate of 1·[illegible] per 1000, which corresponded with the mean rate during the week under notice from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 20 and 27 in the two preceding weeks declined again to 20, and included eight in Glasgow, five in Paisley, four in Edinburgh, and three in Dundee. The 12 deaths from whooping-cough exceeded the number in the previous week by one, and included eight in Glasgow and two in Aberdeen. The deaths referred to diarrhœa, which had been 20, 17, and 12 in the three preceding weeks, rose again to 15, and included five in Glasgow and two each in Edinburgh, Dundee, Paisley, and Perth. The two deaths referred to "fever" were returned in Dundee and Greenock. The fatal cases of diseases of the respiratory organs in the eight towns, which had been 124 and 103 in the two preceding weeks, rose during the week under notice to 142, and exceeded by 25 the deaths referred in these towns to the same diseases in the corresponding week of last year. The causes of 20, or rather more than 3 per cent., of the deaths registered in these eight towns were not certified, against 1 per cent. in the 76 English towns.

The annual rate of mortality in eight of the principal cotch towns, which had been 18·0, 18·9, and 19·4 in the hree preceding weeks, declined to 19·1 during the week nding April 14th, but exceeded by 2·0 the mean rate uring the same week in the 76 large English towns. he rates in the eight Scotch towns ranged from 1·6 and 14·4 in Aberdeen and Paisley to 20·2 in eith, 20·9 in Glasgow, and 24·3 in Greenock. The 55 deaths in these eight towns included 23 which ere referred to measles, 12 to whooping-cough, 11 to iarrhœa, seven to diphtheria, one to "fever," but not one ither to scarlet fever or to small-pox. In all, 54 deaths esulted from these principal infectious diseases last week, gainst 62 and 51 in the two preceding weeks. These 54 eaths were equal to an annual rate of 1·6 per 1000, which as 0·1 below the mean rate last week from the same iseases in the 76 large English towns. The fatal cases of easles, which had been 27 and 20 in the two previous weeks, ose again last week to 23, of which 12 occurred in Glasgow, ix in Edinburgh, three in Dundee, and two in Leith. The 12 fatal cases of whooping-cough corresponded with the umber in the previous week, including six in Glasgow, three in Leith, two in Edinburgh, and one in Dundee. The 11 eaths attributed to diarrhœa showed a decline of four from the previous week; seven were recorded in Glasgow, two in Dundee, and one both in Edinburgh and Leith. Of the seven fatal cases of diphtheria, showing an increase of six upon the number in the previous week, five occurred in Glasgow and two in Edinburgh. The deaths referred in the eight towns to diseases of the respiratory organs, which had been 103 and 142 in the two previous weeks, further rose last week to 170 and exceeded by 53 the number returned from these diseases in the corresponding week of last year. The causes of 25, or nearly 4 per cent, of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been 23 1, 25·6, and 26·1 per 1000 in the three preceding weeks, declined again to 21·1 during the week ending April 7th, but exceeded by 4 per 1000 the mean rate during the same period in the 76 English towns. During the 13 weeks of last quarter the death-rate in Dublin averaged 22 9 per 1000, whereas during the same period the mean death-rate did not exceed 16 6 in London and 17·4 in Edinburgh. The 153 deaths of persons belonging to Dublin registered during the week under notice were fewer by 37 than the number in the previous week and included but four which were referred to the principal infectious diseases, against ten in the preceding week; of these, two resulted from whooping-cough and one each from measles and diarrhœa. The four deaths from these infectious diseases were equal to an annual rate of 0 6 per 1000, against 1 6 and 1·5 from the same diseases in the week under notice in London and Edinburgh respectively. The two fatal cases of whooping-cough in Dublin corresponded with the number in the previous week; and the death from measles was the first recorded in the city since the beginning of the year. The 153 deaths registered in Dublin included 22 of infants under one year of age and 47 of persons aged upwards of 60 years; both these numbers showed a marked decline from the numbers in recent weeks. Four inquest cases and two deaths from violence were registered; and 62, or no less than 41 per cent. of the 153 deaths, were recorded in public institutions. The causes of nine, or nearly 6 per cent., of the deaths registered in Dublin during the week under notice were not certified.

The death-rate in Dublin, which had been 25·6, 26·1, and 21·1 in the three preceding weeks, rose again to 23·4 in the week ending April 14th. During the 13 weeks of last quarter the death-rate in the city averaged 22·9 per 1000, whereas the mean death-rate during the same period did not exceed 16·6 in London and 17 4 in Edinburgh. The 170 deaths of persons belonging to Dublin registered during the week under notice showed an increase of 17 upon the number returned in the previous week, and included six which were referred to the principal infectious diseases, against ten and four in the two preceding weeks; of these, three resulted from whooping-cough, one each from measles, "fever," and diarrhœa, and not any from either small-pox, measles, or diphtheria. The six deaths from these infectious diseases were equal to an annual rate of 0·8 per 1000, the death-rate last week from these diseases being 1·6 in London and 1·7 in Edinburgh. The three fatal cases of whooping-cough in Dublin exceeded the numbers in recent weeks. The 170 deaths included 21 of infants under one year of age and 53 of persons aged upwards of 60 years; the deaths of infants showed a further decline from the numbers in recent weeks, while those of elderly persons showed an increase. Six inquest cases and three deaths from violence were registered; and 71, or 42 per cent., of the 170 deaths were recorded in public institutions. The causes of seven, or more than 4 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: E. St. M. Nepean to the *Empress of India;* J. Bradley to the *Royal Oak;* H. W. Macnamara to the *Euryalus;* W. G. Stott to the *Acheron;* J. Jenkins to the *Hood;* W. J. Colborne to the *Russell;* and G. T. Collingwood to the *President*, additional, for three months' hospital course. Staff Surgeons: C. J. E. Cock to the *Thetis* and to the *Perseus*, on recommissioning; H. H. Pearse to the *Vernon*, additional, for the *Furious;* W. K. Hopkins to the *Victory*, for Portsmouth Dockyard; C. L. W. Bunton to the *Triumph*, on recommissioning; H. E. Tomlinson to the *Bedford;* and J. E H. Phillips to the *Royal Arthur.* Surgeons: R. L. Dickinson and A. G. Eastment to the *Pembroke;* W. L. Hawkins to the *Leda;* F. J. Gowans to the *Triumph;* A. D. Spalding to the *Queen;* G. E. Hamilton to the *Vengeance;* W. N. Horsfall to the *Euryalus;* C. A. G. Phipps, to be lent to the *Trafalgar;* G. S. Davidge to the *Thetis;* E. P. G Causton and J. Verdon to the *Pembroke*, for disposal; and W. N. L Cherry to Royal Marine Division, Chatham.

ROYAL ARMY MEDICAL CORPS.

Captain M. F. Foulds, from Jubbulpore Brigade, is posted to the Bombay Brigade. Colonel D. Bruce, C.B., of the Army Medical Service Advisory Board, is ordered to Malta for duty with the Mediterranean Fever Commission. Colonel A T. Sloggett, C.M.G., P.M.O., London district, proceeds to Lisbon to attend the International Congress of Medicine as English delegate. Major T. H. F. Clarkson is appointed Medical Officer at the Tower of London.

MILITARY HYGIENE AT ALDERSHOT.

A school of military hygiene has been established at Aldershot under the direction of Lieutenant-Colonel R. H. Firth, R.A.M.C., for the instruction of regimental officers and soldiers. Its aim and object is not only to acquaint them generally with the elementary principles and laws of hygiene but to point out at the same time in a simple and practical way the causes of disease in the army and how best to guard against them. We are very glad that a beginning has been made in what promises to become an extremely useful and desirable object, for, practically speaking, very much depends upon the officers and men of our army, especially on field service, understanding and taking sanitary precautions in sufficient time to make them effective.

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on April 10th, Sir J. Dick, K.C.B., being in the chair, the sum of £55 was distributed among the several applicants.

LEGISLATION IN REGARD TO CHILDREN.—A conference on legislation in regard to children will be opened by the Lord Mayor at the Guildhall, London, on May 22nd and will be continued on the following day. It has been convened by the committee of the International Congress for the Welfare and Protection of Children held in London in 1902 under the patronage of His Majesty the King and H.R.H. the Princess Louise, Duchess of Argyll, with a view to the discussion, in the light of their latest developments, of certain questions which were dealt with at the Congress. It will be attended by members of county councils, boards of guardians and other public authorities, magistrates, school managers, teachers, and those engaged in private charitable effort. The following subjects will be considered in all their aspects alike as to principles and details: (1) the free feeding of school children; and (2) children's courts, probation officers, and remand homes. The secretary of the executive committee of the conference is Mr. W. G. Lewis, barrister-at-law, 8 Wells-street, Gray's Inn-road, London, W.C.

Correspondence.

"Audi alteram partem."

ON THE PHYSIOLOGICAL DIVISION OF THE PREGNANT UTERUS.

To the Editors of THE LANCET.

SIRS,—In vindication of my claim to originality in the description of the physiological division of the pregnant uterus and its bearing upon the management of labour, I venture to intrude this short note upon THE LANCET. Dr. G. F. Blacker, in his excellent article on the Management of the Third Stage of Labour,[1] makes the following statement: "The upper uterine segment is from two to three times thicker than the lower uterine segment and the site of the ring of Bandl, the so-called retraction ring or the line of union between the two segments, is now apparent." From this it seems that Dr. Blacker has fallen into the error of assigning to Germans the discoveries of Englishmen. The first description of the uterus in its bearing on placenta prævia was made by me in THE LANCET in 1847 and more fully in the publication of my Lettsomian lectures in 1857, and it has been frequently discussed by me on subsequent occasions. The fundamental idea of my theory has been generally adopted. The uterus was divided into three zones: (1) the upper or fundal; (2) the equatorial; and (3) the lower. The fundal zone is divided from the equatorial by an imaginary line, the upper polar circle. This line had not been anatomically demonstrated by anyone but myself. But it seems to mark a distinction which, I believe, is real, between the properties of the upper and lower zones in their relations to placental attachment and to hæmorrhage. The equatorial zone is divided from the lower zone by a line, "*Barnes' boundary line*, 1847–1857," and since distinguished as *Braune's os internum*, 1872, as *Bandl's ring*, 1876, and more recently as *Schroeder's contraction ring*. If priority of discovery and publicity justify a claim to originality I am entitled to protest against the substitution of the term *Bandl's ring* for *Barnes' boundary line*.—I am, Sirs, yours faithfully,

April 16th, 1906. ROBERT BARNES, M.D. Lond.

THE WORKMEN'S COMPENSATION BILL.

To the Editors of THE LANCET.

SIRS,—The Workmen's Compensation Bill having now passed the second reading I append extracts from the printed Bill of such paragraphs as will affect the medical profession. It will be noticed that the medical referees, if the Bill passes in its present form, will be required to give their services on certain occasions instead of being entirely unemployed as under the Act of 1897, for in Paragraph (15) of the first schedule, Subsection (*b*), the "may" which made the Act abortive is changed to "shall." In Subsection (*a*), however, there is still a "may" and also in Paragraph (15) of the second schedule there is "may" again, and unless these "mays" are altered to "shalls" the functions of the medical referees will be curtailed—that is, if the experience of the last seven years is any guide to the attitude of county-court judges to the question of medical referees. It will be seen also that the whole status, remuneration, and methods of performing the examinations they may be called on to make of medical referees will be subject to the regulations made by the Secretary of State. I feel quite sure, however, that before these regulations are made the Secretary of State will have before him full information and that the regulations will harmonise with the ethics of the profession.

I am, Sirs, yours faithfully,
ALBERT BENTHALL, F.R.C.P. Edin.

Haverstock hill, N.W., April 12th, 1906.

Extracts from the Workmen's Compensation Bill, 1906.

II. (1) The Secretary of State *may* appoint such legally qualified medical practitioners to be medical referees for the purposes of this Act as he may with the sanction of the Treasury determine, and the remuneration of, and other expenses incurred by medical referees under this Act shall, subject to regulations made by the Treasury, be paid out of moneys provided by Parliament.

First Schedule.—Scale and conditions of Compensation.—(4) Where a workman has given *notice* of an accident he shall, if so required by the employer, submit himself for examination by a duly qualified medical practitioner provided and paid by *the employer, and if he refuses to* submit himself to such examination, or in any way *obstructs* the same, his right to compensation, and any proceeding under this Act in relation to compensation, shall be *suspended until such* examination has taken place

(14) Any workman receiving weekly payments under this Act shall, if so required by the employer, *from time to time* submit himself for examination by a duly qualified medical practitioner provided and paid by the employer. If the workman refuses to submit himself to such examination or in any way obstructs the same, his right to such weekly payments *shall be suspended* until such examination has taken place.

(15) A workman shall not be required to submit himself for examination by a *medical practitioner* under paragraph (4) or paragraph (14) of this schedule *otherwise* than in accordance with regulations made by the Secretary of State, or at more frequent intervals than may be prescribed by those regulations. Where a workman has so submitted himself for examination by a medical practitioner and *the employer* has within six days after such examination furnished the workman with a copy of the report of that practitioner as to his condition, then in the event of no agreement being *come to between* the employer and the workman as to the workman's condition or fitness for employment, the *registrar of* the county court on application being made to the court by either party: (*a*) may, on payment by the applicant of such fee not exceeding two pounds as may be prescribed in the case of a submission for examination under paragraph (4) of the schedule; and (*b*) shall without any fee in the case of a submission for examination under paragraph (14) of this schedule, refer the matter to a medical referee. The medical referee *to whom the matter is so referred shall, in accordance with regulations* by the Secretary of State, give a certificate as to the condition of the workman and his fitness for employment, specifying, where necessary the kind of employment for which he is fit, and that certificate shall be conclusive evidence as to the matters so certified. If a workman on being required so to do refuses to submit himself for examination by a medical referee to whom the matter has been so referred as aforesaid, or in any way obstructs the same, his right to compensation, and any proceeding under this Act in relation to compensation, or in the case of a workman in receipt of a weekly payment his right to that weekly payment, *shall be suspended until such examination* has taken place. Rules of court may be made for prescribing the manner in which documents are to be furnished or served and application made under this paragraph and the forms to be used for those purposes and, subject to the consent of the Treasury, as to the fee to be paid under this paragraph

Second Schedule.—Arbitration.—(15) Any committee, arbitrator, or judge may, subject to regulations made by the Secretary of State and the Treasury, appoint a medical referee to report on any matter which seems material to any question arising in the arbitration.

ANTERIOR OR POSTERIOR GASTRO-JEJUNOSTOMY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 14th, p. 1071, Mr. B. G. A. Moynihan asks, "Is there any surgeon who has a moderate experience of both operations who prefers the anterior method?" As one who possesses such experience I reply to his query in the affirmative. I have repeatedly practised the posterior no-loop method with uniformly good results. I have also in a very much larger number of instances performed the anterior operation and I prefer it. Like Mr. Moynihan, I have no cases of regurgitant vomiting nor do I think this untoward sequel will occur after the anterior operation if the jejunum is fixed to the stomach for a short distance beyond either end of the anastomotic opening. I attach some importance to the position of the opening in the jejunum, making it midway between the mesenteric and anti-mesenteric borders on the right side of the intestine. This position allows the jejunum to be applied to the stomach without twisting it on its *longitudinal axis*. It is claimed for the posterior method that it gives a dependent opening; so does the anterior operation if this opening is made, as it should be, flush with the great curvature. To secure this it is permissible to ligature one or more of the vessels running over the lower part of the anterior wall of the stomach.

I have no experience of post-operative jejunal ulceration in a series of more than 100 anterior gastro-jejunostomies, but I freely admit that, according to our present views of the causation of this undesirable sequel, it should occur less frequently after the posterior operation. On the other hand, the anterior method is simpler and therefore easier to perform; it involves less exposure and handling of the transverse colon and omentum and a smaller risk from shock and peritoneal soiling, and in the event of peritoneal infection it permits of direct drainage, whereas in the posterior method the operator has "burnt his boats" should this dire calamity supervene. Both operations when properly performed give admirable results and are wonderfully safe; indeed, it may be permitted to doubt whether there is much to choose between them, and what there is is probably overshadowed by the rsonal equation of the operator. Most will agree that, her things being equal, simplicity counts for something in rgery, and it is the greater simplicity of the anterior eration which appeals to me.

---

I am, Sirs, yours faithfully,

Sheffield, April 14th, 1906. SINCLAIR WHITE.

IN PRAISE OF RUM AND MILK.

To the Editors of THE LANCET.

SIRS,—In the midst of the clamour and distracting claims the advocates of whisky and brandy, of wine and bitter er, of "pot stills" and "patent stills," and of endless her forms and devices of alcohol, to be used for strictly edical purposes only, I venture to put in a word on behalf my venerable old friend, good Jamaica rum. Not, be it marked by way of *caveat*, in its natural and unregenerate ate—for even reforming "Jack" is giving it up as a verage and finds he is much better without it—but when arried to milk, in a combination which, like all well-assorted ions, brings out to advantage the good qualities of both rties to the alliance. A pretty long experience of the rtues of this ancient preparation emboldens me to say that doctors who find it necessary to prescribe alcohol as a imulant to their patients, for which purpose it is often valuable, would do so in the form of rum and milk there ould be far less risk than there is with other alcoholic verages of the use of the remedy being perpetuated as an dispensable indulgence. There is no form in which alcohol so easily tolerated by even the most fastidious stomach as that of rum and milk and the indigestion *must be a very* opeless one which will not yield to a diet of a small cup of arm milk to which a teaspoonful of rum has been added, llowed by a plain biscuit or two and some very mild cheese, aradoxical as this combination may seem.

I know that many people, especially those of superfine iste and with fancied delicacy of digestion, will exclaim hen such a diet is prescribed to them that they cannot bide either rum or cheese. And I must confess that there rather a haze of vulgarity about both of them. But apart om this very venial defect, which might be cured by dubbing ne *lait au rhum* and the other *fromage dyspeptique*, the ause of their dislike probably is that they have been in the abit of taking too much of them or not taking them in a dicious form. Taken wisely and not too well they will be ound hard to beat, by the dyspeptic as well as by the convalescent from sickness, for use as a happy combination of timulant and nutriment which is much less costly and more ustaining than any of the numerous alcoholic "pick-me-ps" which are now so sedulously forced under the noses of e profession.

I am, Sirs, yours faithfully,

Gloucester, April 15th, 1906. FRANCIS T. BOND, M.D. Lond.

THE STATUS OF THE HAMPSTEAD GENERAL HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Will you allow me to supplement your annotation egarding the above with a little more detailed information or the benefit of your readers, as I think they are likely to ather an incorrect impression from it? Although the ospital has recently been moved into larger and more suitble buildings than those formerly occupied there has hitherto een no change made in its constitution and management. or the past 12 years the hospital has drawn its patients from Hampstead, Highgate, Hendon, and the adjoining neighourhood," the latter including Gospel Oak and West Hampead. The out-patient department has been in existence for ver ten years, and there have been free beds as well as conributory beds for 12 years. With regard to these latter, I elieve this institution is the pioneer of what I venture to ope may become the common practice in all London ospitals, with the exception of the 13 teaching hospitals—z, the *establishment of contributory beds with the right to he patient to bring in his own doctor* to attend him, it always eing understood that inquiry is made of the patient as to is means, on the one hand, and, on the other, that the octor partakes in the giving of charity by meeting the eans of the patient in the matter of fees. I believe this rrangement if adopted universally would meet Mr. Sydney olland's views without founding any new institutions for he purpose.

Further, we have had inquiry made into the means of those applying for out-patient relief for the last eight years. Those families in which the total wage-earnings amount to 5*s.* per head per week or under are considered suitable cases; where this basis is exceeded each case is considered upon its merits; those deemed unsuitable are referred to the provident dispensaries or sent back to their private medical attendant. Since the dispensary patients get no benefit until they have been members for a month, and since the majority of such cases as we send on cannot pay the 5*s.* demanded by them to secure immediate attendance, it is arranged that they may attend the hospital during that month provided they bring evidence to show that they have joined the dispensary, and then at the end of the month they are sent over to the dispensary medical officer with a letter saying what has been done for them. Such a system is, I imagine, only possible in a small out-patient department. I fear that Mr. Humphreys will have conveyed to your readers in his letter of a week or two ago that we have a vast army of out-*patients attending the hospital.* That is not so; and I believe that it is entirely due to the inquiry and the letter system in vogue that the numbers are kept down. It seems, in my opinion, to be the only good point to be said in favour of any letter system that the difficulty of getting letters tends to keep the numbers down. Last year the out-patients numbered 1766; accidents, 646; and dental cases, 91. The total attendances made were 7550. Those who know the number of attendances at a respectably sized out-patient department in London will agree with me that 20,000 is a very ordinary number and therefore we are well below the mark. Assuming, therefore, that out-patient departments are permissible in hospitals I submit that there is not a *casus belli* upon this point in connexion with the Hampstead General Hospital.

As to casualties, the following regulation is in force:—

> Casualty cases are to comprise only urgent medical and surgical cases. Such cases are to be attended for two days only and to be then referred to the out patient department and directed to procure letters for the same or a doctor's visiting card in lieu thereof.

This has been in force since November, 1902, and these cases are questioned as to means when they come under the inquiry officer in the out-patient department. With regard to "the comparatively well-to-do patients" which you suggest inhabit the wards of the hospital I can assure you, from my experience in other institutions, that our patients are of the usual type found in metropolitan hospitals, no better and no worse.

I hope your readers will infer that beyond increasing the number of available beds the move into the new buildings has not so far led to any changes which justify the phrase, "it has now developed into a general hospital." It has been a general hospital, in fact, for the past 12 years, though the actual name was only adopted a few years back and then for good reasons. I regret that my amendment was not carried at the recent meeting of the division of the British Medical Association to which you refer. There appears to be a reform party who aim at abolishing all out-patient departments in London. I cannot agree with that policy nor can I understand why they have commenced their operations with one of the smallest and least abused out-patient departments in London. I do not yet know which institution will be the next one to come under the ban, but with yourselves, doubtless, will await the disclosure with interest.

I am, Sirs, yours faithfully,

Belsize-park, N.W., April 17th, 1906. LEWIS G. GLOVER.

A COUNTERBLAST TO TOBACCO.

To the Editors of THE LANCET.

SIRS,—The proposed legislation, so far as I can see, would not stop juvenile smoking. Boys would smoke in the streets as they do at present and no one would have any right to interfere with them. No conviction of a seller would be possible except from the evidence either of the purchaser himself or of a bystander and such evidence would rarely be procurable. The bystander would be easily eliminated from the transaction and the juvenile smoker might be trusted not to dry up the sources of his illicit gratification. A legislative assembly capable of passing such an enactment might rightly be called the grandmother, rather than the mother, of Parliaments and would be doing pretty nearly as much as was possible within the four corners of a single Act to bring all law and order into disrepute. The most effective methods of preventing juvenile smoking would be those adopted by that able officer of His Majesty's navy, Mr. Falcon, as recounted by Peter Simple, but it is to be feared that modern sentiment would not allow such obvious interference with the liberty of the subject.

Apart from the futility of the particular measure the question of the desirability of interference with juvenile smokers, and especially of interference to be confined within a new and arbitrary age limit, is one that calls for careful consideration. If there is to be interference at all, why should it cease at the age of 16 years and why should it not extend to the period at which young people become legally independent and responsible in all other directions? The sole basis of the proposed legislation is that smoking is believed to be injurious to the bodies of the immature, just as extravagance would be injurious to their estates. A minor is not allowed by law to dissipate his estate; why should he be allowed to persist in an indulgence which would dissipate his health? The positive evidence which we possess of the poisonous action of tobacco is mostly, if not entirely, furnished by adults. The subjects of tobacco blindness are usually men in middle life and it is, perhaps, rare to recognise tobacco as a cause of any definite ailments under 30 years of age. Lord Roberts has recently sent a message to the boys of Birmingham in which he tells them that they cannot be "thoroughly fit" if they begin smoking when they are growing lads. He adds that smoking affects the nerves and prevents a boy from becoming a good rifle shot. It affects the heart and may render the boy incapable of undergoing the hardships of active service when he is grown up. Lord Roberts, no doubt, is absolutely convinced of the accuracy of these statements, and I am so far from desiring to question them that I think they are very probably well within the truth. But if they are true for growing lads they are probably true also, if possibly in a less degree, for adults. Lord Roberts advises boys not to smoke until they have passed the age of 18 years, while Dr. Macnamara's Bill would fix 16 years as the age for commencement. What is the evidence in favour of either limit? or what reason is there to believe that a practice which is injurious at 17½ years of age would be harmless or even beneficial six months later?

Are we not in need of careful physiological inquiry into the action of tobacco, and do we really know much about it beyond the admitted facts that it is highly injurious in a certain proportion of smokers, and apparently harmless to the majority, who, moreover, would not pursue an expensive habit unless they derived some sort of gratification from it? Many persons are of opinion that a race which had grown up outside the influence of narcotics would be in every respect better, stronger, more capable, and, in a word, more manly, than a race which had become dependent upon them; and it is certain that history would not assign to the users of such agents a high position among the rulers of the world. Looking beyond quite modern times, the Turks have been the greatest consumers of tobacco and the Hindoos and Chinese of opium, and the examples set by these nations are not entirely encouraging to those who follow them. Neither the heavy smokers of our own day nor the habitual consumers of morphine, of cocaine, or of other vegetable narcotics are likely to be largely contributory to the success of the Imperial idea, and if we put aside preconceptions arising from personal tastes or social habits it is difficult not to conclude that the undrugged man is likely to be in all respects better than the drugged one. The history of opinion upon the subject is far from being satisfactory and it is high time that opinion was replaced by knowledge. A physiological inquiry into the action of tobacco, if carefully and impartially conducted, would be likely to furnish results of much practical value to mankind.

I am, Sirs, yours faithfully,
F.R.C.S.

April 9th, 1906.

THE ARMY MEDICAL RESERVE.

To the Editors of THE LANCET.

SIRS,—The idea of forming a Royal Army Medical Corps reserve out of young surgeons who would be obliged to go through a definite course of training may be a very good one, although it remains to be seen how the method will work when put into operation, the first essential to its origin being the supply of men to train. Will enough men be found to devote the time not only for initial but for annual training? For as years went on medical men would not find it easy to leave their work for a month in the year to be devoted solely to military reserve training. But what about the hundreds of civil surgeons who went through a long training and gained experience in the South African war? Why is there no scheme to utilise the services of men who received not one month in a year but 12 months or more of active service abroad? It cannot be that these were of no use and that they did not gain experience. It would appear that there is a reserve ready made if the War Office would but bring it out—at least, amongst such men as obtained satisfactory reports for services rendered. The War Office should have created a strong Royal Army Medical Corps reserve after the South African war of men who had seen hard and long training and service.

I am, Sirs, yours faithfully,
WAR DOG.

THE FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

(FROM OUR SPECIAL COMMISSIONER.)

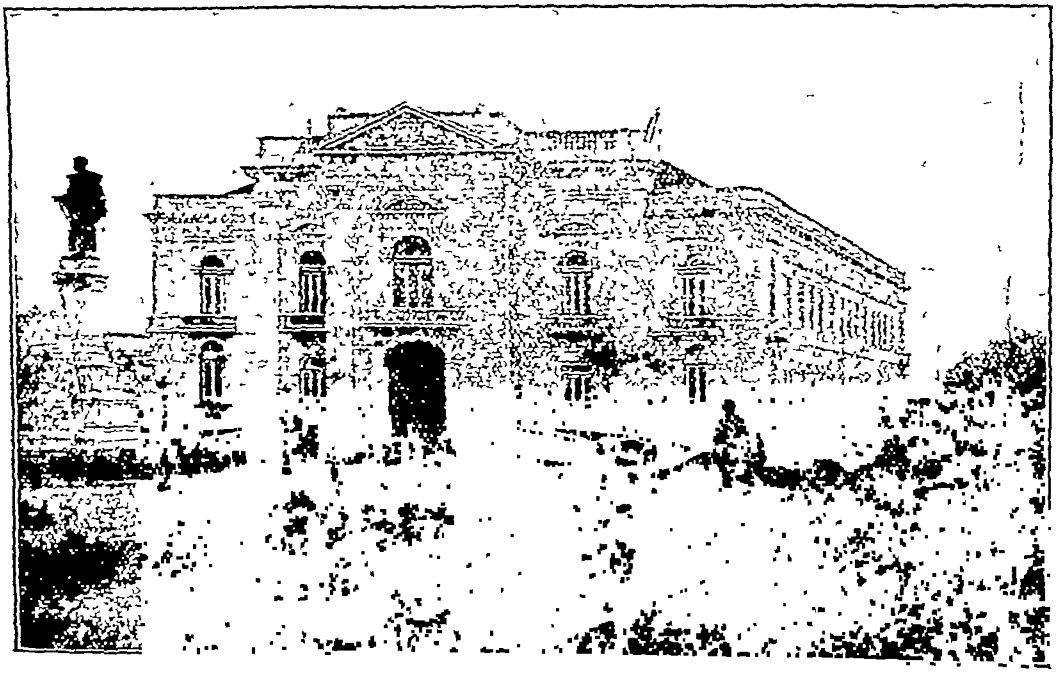
Lisbon, April 12th.

WHAT THERE IS TO BE SEEN AND STUDIED AT LISBON.

THE members of the International Congress of Medicine will find that apart from the debates and business of the 17 sections there is much to observe and study in Portugal. All travellers have admired the beauty of the site, the aspect of the seven hills now comprised within the extended boundary of Lisbon, and the majestic expanse of the Tagus, with its many ships of war and of peace lying at anchor in front, and, as it were, at the very feet, of the ancient capital. The quaint, steep, winding, narrow, old streets, the broad tree- and flower-planted modern avenues, these and many other characteristic features of the capital of Portugal will not fail to charm and to impress the visitor. But apart from such general attractions the members of the Congress will find a great deal that is of special technical interest to them as medical men and as sanitary reformers.

It is, indeed, curious how little seems to be known in England about Portugal. Certainly it is but a small country, yet in the periodical literature of England, the newspapers and the magazines, articles and dissertations abound about such small countries as Holland, Belgium, and Switzerland. On the other hand, Portugal is but rarely mentioned. Perhaps the Fifteenth International Congress of Medicine will help to remedy this omission. If the members can only find time to go about and to investigate some special questions, to visit some of the institutions in which they are particularly interested, they will discover that in many respects Portugal is quite abreast of the times. It may even be said that in some important matters Lisbon leads the way. For instance, how much London would gain if it possessed a model slaughter-house such as that which was built long ago at Lisbon. How extremely interesting also is the long and arduous struggle of the authorities to secure cheap and wholesome meat for the people. Some years ago the cattle-dealers formed a "ring" or "combine" so as to control the market. Instead of competing with one another they agreed to pay less for cattle and to increase the sale price of meat. Thus they won on both sides and this at the cost of the cattle-breeders and of the consumers of meat. Thereupon the municipality thought it would break up this "combine" by itself buying cattle and selling meat. Municipal butchers' shops were therefore opened in various parts of the town and even hawkers were sent round to sell the municipal meat on barrows. The cattle-breeders, however, failed to appreciate this action, though it was intended to protect their interests. Instead of supporting the municipality they allied themselves with the cattle-dealers and so arranged matters that the municipality had to pay a very high price for the cattle which it bought; on the other hand, as the municipality sold the meat very cheaply it soon incurred a heavy loss. But the greatest disappointment of all was the fact that hardly any poor people profited by this action; they rarely got hold of any of the municipal meat. It was for the most part bought up by hotel keepers and people who were rich enough to bribe the intermediaries. A special municipal committee was then appointed to investigate the question

After a long inquiry the present system was instituted. A sort of monopoly was offered and tenders were invited. The concessionaire or monopolist would be the sole person authorised to buy cattle, but, on the other hand, he had so to arrange matters that the meat could be retailed to the public at an average price of about 10*d.* per pound. A regular tariff is established in regard to the various parts of meat and the retail price at which it is to be sold. The number of butchers' shops allowed is limited and the police watch constantly to see that the meat is sold at the prices fixed by the tariff But the object was not only to prevent such speculations and combinations as would tend to increase the retail price of meat; it was also thought desirable to encourage the home breeders of cattle. Therefore the concessionaire was also bound down by the terms of the contract to purchase his cattle from the Portuguese cattle-breeders. If, however, through some exceptional or other circumstance—the shortage of supply or the outbreak of cattle disease—Portuguese cattle becomes too dear for the meat to be retailed at the regulation price then the concessionaire is allowed to import cattle from abroad and this without having to pay any duty. Finally, in case of extreme emergency, the importation of frozen meat would be sanctioned. But this latter contingency is considered so improbable and viewed with so much dislike that no cold storage rooms exist at the slaughter-house. It would be necessary to build such places before frozen meat could be imported. Therefore visitors to Lisbon will enjoy fresh meat and will not be called upon to eat any cold storage meat.



The School of Medicine, Lisbon, where the Congress holds its meetings.

In this arrangement, however, two important and dominating factors were not taken into consideration. It was forgotten that as it was almost impossible to prevent Spanish cattle straying over into Portugal and Portuguese cattle wandering away into Spain, causing any amount of frontier disputes and "incidents," a *treaty* had been concluded abolishing all duties on cattle between the two countries. The second omission was *that* no account was taken of the varying value of gold. Some years ago, when Portuguese credit was at a low ebb, the Spaniard, with cheaper gold, had every advantage in buying cattle in Portugal. But in time the conditions altered, gold became cheaper in Portugal; there was a moment during the war between Spain and the United States of America when gold was at 100 per cent. premium in Madrid, and even to-day it is at 30 per cent. premium. *Therefore it is the Portuguese* who have every advantage in buying Spanish cattle, particularly if these can be passed off as Portuguese cattle and sold at the enhanced price artificially created so as to encourage cattle breeding in Portugal. Thus now a great discussion has arisen as to what constitutes a cattle breeder. There is a cattle market not far from the slaughter-house. Here there is, and can be, only one purchaser, but there are many to sell. Here the live cattle are inspected by veterinary surgeons and the one purchaser has every interest to see that cases of disease are detected; he has also every interest to prove that the cattle are not home bred, because if there are not enough Portuguese cattle he may bargain and beat down the price of imported cattle. Having secured the necessary amount of cattle the concessionaire has to hand them over to the municipal authorities at the slaughter-house and pays them for killing. This, from the public health point of view, is the most important part of the proceeding. All the slaughterers, all the workers who prepare the meat and carry out the multifarious other processes connected with the killing of animals for food, are employed by the municipality. No one has any interest to serve in saving from destruction any unwholesome meat. The retail butcher who, by the way, is not a butcher since he does not kill, has every interest in having only sound meat, since it does not come from his own cattle. The butcher has no cattle, he is *simply a tradesman*, and his only interest is in so satisfying his customers so as to keep them and increase their number. *Thus* it will be seen that, whatever criticism may be made of the present system, it in any case contributes very *materially* to secure wholesome food for the public. The concession described above, it must be added, only applies to cattle that produce beef and veal. For hogs and sheep anybody may buy or sell, but no one must kill. If an individual was to kill his own pig or sheep he would be severely punished. At the municipal slaughter-house only, and by the municipal employees, is the killing of any animal for food allowed. No one may do this work who has the slightest interest in passing on to the public unwholesome meat. The consumption of meat at Lisbon amounted in 1898 to an average of 31·7 kilogrammes per inhabitant. In possible within the four corners of a single Act to bring all law and order into disrepute. The *most* effective methods of preventing juvenile smoking would be those *adopted* by that able officer of His Majesty's navy, Mr. Falcon, as recounted by Peter Simple, but it is to be feared that modern sentiment would not allow such obvious interference with the liberty of the subject.

Apart from the futility of the particular measure the question of the desirability of interference with juvenile smokers, and especially of interference to be confined within a new and arbitrary age limit, is one that calls for careful consideration. If there is to be interference at all, why should it cease at the age of 16 years and why should it not extend to the period at which young people become legally independent and responsible in all other directions? The sole basis of the proposed legislation is that smoking is believed to be injurious to the bodies of the immature, just as extravagance would be injurious to their estates. A minor is not allowed by law to dissipate his estate; why should he be allowed to persist in an indulgence which would dissipate his health? The positive evidence which we possess of the poisonous action of tobacco is mostly, if not entirely, furnished by adults. The subjects of tobacco blindness are usually men in middle life and it is, perhaps, rare to recognise tobacco as a cause of any definite ailments under 30 years of age. Lord Roberts has recently sent a message to the boys of Birmingham in which he tells them that they cannot be "thoroughly fit" if they begin smoking when they are growing lads. He adds that smoking affects the nerves and prevents a boy from becoming a good rifle shot. It affects the heart and may render the boy incapable of undergoing the hardships of active service when he is grown up. Lord Roberts, no doubt, is absolutely convinced of the accuracy of these statements, and I am so far from desiring to question them that I think they are very probably well within the truth. But if they are true for growing lads they are probably true also, if possibly in a less degree, for adults. Lord Roberts advises boys not to smoke until they have passed the age of 18 years, while Dr. Macnamara's Bill would fix 16 years as the age for commencement. What is the evidence in favour of either limit? or what reason is there to believe that a practice which is injurious at 17½ years of age would be harmless or even beneficial six months later?

Are we not in need of careful physiological inquiry into the action of tobacco, and do we really know much about it beyond the admitted facts that it is highly injurious in a certain proportion of smokers, and apparently harmless to the majority, who, moreover, would not pursue an expensive habit unless they derived some sort of gratification from it? Many persons are of opinion that a race which had grown up outside the influence of narcotics would be in every respect better, stronger, more capable, and, in a word, more manly, than a race which had become dependent upon them; and it is certain that history would not assign to the users of such agents a high position among the rulers of the world. Looking beyond quite modern times, the Turks have been the greatest consumers of tobacco and the Hindoos and Chinese of opium, and the examples set by these nations are not entirely encouraging to those who follow them. Neither the heavy smokers of our own day nor the habitual consumers of morphine, of cocaine, or of other vegetable narcotics are likely to be largely contributory to the success of the Imperial idea, and if we put aside preconceptions arising from personal tastes or social habits it is difficult not to conclude that the undrugged man is likely to be in all respects better than the drugged one. The history of opinion upon the subject is far from being satisfactory and it is high time that opinion was replaced by knowledge. A physiological inquiry into the action of tobacco, if carefully and impartially conducted, would be likely to furnish results of much practical value to mankind.

I am, Sirs, yours faithfully,
F.R.C.S.

April 9th, 1906.

THE ARMY MEDICAL RESERVE.

To the Editors of THE LANCET.

SIRS,—The idea of forming a Royal Army Medical Corps reserve out of young surgeons who would be obliged to go through a definite course of training may be a very good one, although it remains to be seen how the method will work when put into operation, the first essential to its origin being the supply of men to train. Will enough men be found to devote the time not only for initial but for annual training? For as years went on medical men would not find it easy to leave their work for a month in the year to be devoted solely to military reserve training. But what about the hundreds of civil surgeons who went through a long training and gained experience in the South African war? Why is there no scheme to utilise the services of men who received not one month in a year but 12 months or more of active service abroad? It cannot be that these were of no use and that they did not gain experience. It would appear that there is a reserve ready made if the War Office would but bring it out—at least, amongst such men as obtained satisfactory reports for services rendered. The War Office should have created a strong Royal Army Medical Corps reserve after the South African war of men who had seen hard and long training and service.

WAR DOG.

April 9th, 1906.

THE FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

(FROM OUR SPECIAL COMMISSIONER.)

Lisbon, April 12th.

WHAT THERE IS TO BE SEEN AND STUDIED AT LISBON.

THE members of the International Congress of Medicine will find that apart from the debates and business of the 17 sections there is much to observe and study in Portugal. All travellers have admired the beauty of the site, the aspect of the seven hills now comprised within the extended boundary of Lisbon, and the majestic expanse of the Tagus, with its many ships of war and of peace lying at anchor in front, and, as it were, at the very feet, of the ancient capital. The quaint, steep, winding, narrow, old streets, the broad tree- and flower-planted modern avenues, these and many other characteristic features of the capital of Portugal will not fail to charm and to impress the visitor. But apart from such general attractions the members of the Congress will find a great deal that is of special technical interest to them as medical men and as sanitary reformers.

It is, indeed, curious how little seems to be known in England about Portugal. Certainly it is but a small country, yet in the periodical literature of England, the newspapers and the magazines, articles and dissertations abound about such small countries as Holland, Belgium, and Switzerland. On the other hand, Portugal is but rarely mentioned. Perhaps the Fifteenth International Congress of Medicine will help to remedy this omission. If the members can only find time to go about and to investigate some special questions, to visit some of the institutions in which they are particularly interested, they will discover that in many respects Portugal is quite abreast of the times. It may even be said that in some important matters Lisbon leads the way. For instance, how much London would gain if it possessed a model slaughter-house such as that which was built long ago at Lisbon. How extremely interesting also is the long and arduous struggle of the authorities to secure cheap and wholesome meat for the people. Some years ago the cattle-dealers formed a "ring" or "combine" so as to control the market. Instead of competing with one another they agreed to pay less for cattle and to increase the sale price of meat. Thus they won on both sides and this at the cost of the cattle-breeders and of the consumers of meat. Thereupon the municipality thought it would break up this "combine" by *itself* buying cattle and selling meat. Municipal butchers' shops were therefore opened in various parts of the *town* and even hawkers were sent round to sell the municipal meat on barrows. The cattle-breeders, however, failed to appreciate this action, though it was intended to protect their interests. Instead of supporting the municipality they allied themselves with the cattle-dealers and so arranged matters that the municipality had to pay a very high price for the cattle which it bought; on the other hand, as the municipality sold the meat very cheaply it soon incurred a heavy loss. But the greatest *disappointment* of all was the fact that hardly any poor people profited by this action; they rarely got hold of any of the municipal *meat*. It was for the most sanitary stables. They look very sleek and healthy. Of course many other animals are kept on the premises. Of the patients, the most numerous come to be treated for hydrophobia. In 12 years 9547 persons were treated for bites from animals believed to be suffering from rabies. There are also wards for the treatment of children suffering from diphtheria, which is unfortunate, for there is no advantage, and perhaps some risk, in having so infectious a disease in the same building as the bacteriological institute. It is true that elaborate precautions are taken but it would be much preferable to send these children to an isolation fever hospital which is well away from the centre of the town and from other buildings.

The Institute of Hygiene, the School of Tropical Medicine, the Sanitary Department and services at the Ministry of the Interior, the control of the bread- and milk-supply, as well as that of the meat-supply, all are matters of great interest. In regard to milk, it is said that formerly as many as 60 pet cent. of samples examined were found to be defective or adulterated. But on August 23rd, 1902, a decree was published by the Minister of the Interior in regard to the collection of samples of alimentary substances and adding to ordinary penalties the posting on the front of the shop an announcement of the verdict pronounced against the shopkeer. As a result, of 100 samples of milk now collected only three or four are found to be defective. There is another excellent law forbidding the sale by pawnshops of second-hand clothes till they have been disinfected and there are such stringent regulations to prevent the spread of tuberculosis that, in many instances, they cannot be applied. Also there are new and improved methods of disinfection and of dealing with passengers, ships, and merchandise coming from ports where plague, yellow fever, or cholera prevails. These are all matters which must be dealt with in detail. For the moment I can only urge that what I have already seen leads to the conclusion that there is something to be learnt from such investigations; and those who choose to profit by the opportunity will not be disappointed with their visit to Lisbon.

THE LATEST NEWS OF THE CONGRESS.

At a late hour this evening the exact number of subscriptions received from members of the Congress was 1451 and for ladies accompanying them 414. As there are thus 1865 names already inscribed it is probable that when the eleventh hour arrivals are included the total figure will exceed 2000. Among those who have arrived is Dr. A. Fernandez Cara, who was general secretary of the Fourteenth International Congress of Medicine held at Madrid three years ago. Also a large number of Brazilian medical practitioners landed to-day It is a great rush to get the new School of Medicine ready for the Congress. Last night, however, the electric light was tried and found to work quite satisfactorily. Never before, I think, will a Congress have met in such absolutely new premises.

The programme of the fêtes is now definitely decided. The inaugural ceremony will take place at 2 P.M. on Thursday, April 19th, and there is to be a reception by Councillor Costa Alemão, President of the Congress. On the next day a garden party will be given by the Visconde Monserrate at Cintra, though how his beautiful grounds are to be reached by many members of the Congress remains a mystery, as at Cintra there are but few carriages available. On April 21st the King will entertain at dinner the official representatives of the various Governments who have been deputed to attend the Congress. On Sunday there will be what is likely to prove the most pleasurable of all the excursions. The members will proceed on a flotilla of steamers on the Tagus to Villa Franca; there they will be entertained at a Portuguese bull-fight, where. as is known, every care is taken that bull, horses, and men are not hurt. On Monday afternoon, the 23rd a concert will be given to the ladies at the Zoological Gardens and in the evening there will be a soirée for all the members at the premises of the Geographical Society. Here, Portuguese national songs will be rendered and there will be dissolving views of the principal places of interest in Portugal. On the 24th the King will give a garden party to all the members of the Congress at the Palace of Necessidades. In the evening the Government will receive the delegates of the Governments, the schools of medicine, and scientific societies. Finally, on Wednesday, April 25th, the municipality will hold a reception at the town-hall. It will be all the easier to profit by these invitations as the sections will not meet in the afternoon but are summoned for the impossible hour of 8.30 in the morning and are expected to continue to sit till 2 or 3 P.M. without any adjournment.

Great disappointment is felt because Professor Behring has announced that he is too ill to attend. His paper on Infectious Diseases among Children will have to be read by someone else. Also the absence of Professor Brouardel will be greatly deplored. He is suffering from pulmonary congestion and is nursing himself at Antibes on the French Riviera.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Birmingham Lying-in Charity.

A YEAR ago the ticket system was abolished in this charity and was replaced by the adoption of a registration fee of half-a-crown. The result has been advantageous to the hospital, for it has received from the fees an additional income of £155 15s., whilst the subscription list has remained practically unchanged. The number of cases attended during the year was 1432, or 254 more than in the preceding year and 526 more than the average of the previous ten years. The medical officers were called in 119 times. The experience of the year showed that a further and larger supply of trained and certificated midwives is a necessity. Luckily the hospital is prepared to undertake the training and no other institution in the city can offer advantages equal to those which are associated with this charity. Alderman Cook pointed out that the health committee of the city council had recently investigated the question of the supply of midwives in Birmingham and it was found that of the 221 on the local roll only 21 were certified by examination, 52 could neither read nor write, and many had no conception of the details of that cleanliness which is so essential in the performance of their work. The hospital is not at present large enough for the work which it has to perform and for a time the committee had under consideration the advisability of erecting a new central home in Loveday-street. Plans were prepared but it was found that the scheme was not satisfactory, for the proposed building was too large for the site and sufficient light and air were not obtainable. Fortunately, Mrs. Barrow Cadbury offered the charity a piece of land adjoining the present site. This was a gift of enormous value, for it rendered possible the erection of a satisfactory building provided with sufficient light and air space. The only difficulty which now stands in the way is that of money. The new building will cost about £11,000. The amount at present available is only £7357 and the committee now appeals to the public to provide the remaining £4000. Mr. and Mrs. T. S. Walker have promised £100 contingent upon nine similar gifts and of these four have already been promised. It is unfortunate that this appeal for support, which is so thoroughly well deserved, should have to be made at the same time as the appeal for the Queen's Hospital extension, for the two claims must necessarily clash to a certain extent. Still, it can scarcely be doubted that both will be fully responded to.

The Crippled Children's Union and the Adult Cripples' Guild.

In some respects the institutions the object of which is to aid the crippled should be looked upon as the most deserving of our charities, for though in some cases it is hard to die it is often still harder to live a happy crippled life. I am therefore sorry to hear that the Adult Cripples' Guild will be forced to curtail its efforts unless aid is rapidly forthcoming. It requires monetary aid not only for the continuance of its work but also to wipe out an adverse balance and it requires the assistance of employers of labour who are willing to give a chance of employment to those of its *protégés* who are capable of work. The Adult Guild was formed three years ago, its object being still to keep in touch with the cripples after they leave the Crippled Children's Union at the age of 16 years. It is to be hoped that the necessary help will be forthcoming, for it is obvious that to cast the cripples adrift at 16 years of age after taking care of them, first in a special school and then in the Crippled Children's Union, is an act of sheer cruelty, for the care previously bestowed upon them will only have enabled them to feel more acutely their subsequent distress. During a special study on the hygiene of slaughter-houses I hope to describe in detail the technicalities of the Lisbon slaughter-house together with the abattoirs of several other towns. This will form part of the controversy in regard to the Chicago stockyards. For the moment I will only say that all members of the International Congress of Medicine who take an interest in such public health questions should not fail to visit the model abattoir of Lisbon. They will be all the more surprised with the excellence of the arrangements, the abundance of space, air, and light, when informed that this is no new institution but was built so far back as 1871.

To assist such inquiries the organisers of the Congress have just published an excellent medical guide to Lisbon. Of the map which it contains mention has already been made and there is an excellent index, so that the information desired can be obtained in a moment. First we find statistics as to the climate, followed by vital statistics. In 1886 ten surrounding parishes were added to the city, thus raising the population from 187,404 to 242,297 according to the census of 1878, but in October, 1905, independence was restored to a couple of these parishes, reducing the population of the capital from 311,206 to 298,903 according to the census of 1890. The census of 1900 puts the population down at 356,000, therefore there has been a rapid increase. The death-rate is high, particularly if we consider that the birth-rate does not amount to quite so high a figure. The births were equal to 26·34 per 1000 and the deaths to 26·49 per 1000 of the population. But if these figures were given per district it would be found that a great excess of mortality is confined to the old and picturesque quarters of the town which remain to-day in a condition very similar to that in which they were in the time of the Moors. This district, the Alfama, stretches towards the Tagus on the side of the hill where there still stand the walls of the castle built by the Moors and is well worth a visit. It is a veritable labyrinth of narrow winding streets and ramps or stairs. The inside of the houses is often very dirty but it will be found that greater care is bestowed on the bedding than in the bad slums of the great towns of England. The love of ornamented or embroidered pillow-cases and of clean, attractive bedding is a very estimable characteristic even of the very poorest classes in Portugal. The municipality, on its side, endeavours to sweep out these narrow, unwholesome streets very frequently, but all this is insufficient to counteract the havoc wrought by poverty and ignorance, by overcrowding, and by the want of light and air. The narrowest street I saw was the Beco da Bicha, which gives into the Rua Ste. Michel. It was certainly not more than two feet wide and two people going in contrary directions could not pass each other. Close by, such streets as the Beco dos Captivos or the Beco de Formosa are about four feet wide, so that circulation in both directions is quite feasible. It is this quarter which supplies the largest contingent of cases of tuberculosis.

Appropriately situated on the main road that runs by the waterside and forms the limit of this very poor quarter is one of the five economical kitchens which constitute a very remarkable institution, well worthy of study on the part of the British visitors whose minds have of late been disturbed by what has been said concerning the physical degeneration of the British race and the 12,000,000 British subjects who were stated to be living on the verge of starvation. Here in a spacious hall are many tables and a counter behind which there is a large, bright, clean kitchen. The poor man can come here and Sisters of Mercy will serve him with a mugful of good, wholesome, pure wine and a large piece of bread for 30 reis or about 1½*d.* This is the poorest meal contemplated by the establishment. To be reduced to wine and bread is to be reduced to the lowest stage of poverty, a fact well worth noting by those who have grasped the significance of the action of the French Government in abolishing, as a measure for the promotion of temperance, all taxation on cheap "hygienic drinks," light wines being the principal of such beverages. But in Portugal such taxation is not yet abolished and the natural wines of the country have to pay an *octroi* duty of 1½*d.* the litre to enter the city of Lisbon. It is estimated that the *octroi* duties amount to an average of £1 10*s.* per annum per inhabitant of the city. That is why, even in this charitable institution, a mugful of wine, containing a little less than half a pint, costs as much as 1*d.* For the same price a very large bowl of soup is served and for 2*d.* quite a sufficient helping of meat with rice, or beans, or potatoes is given. Thus a complete meal of wine, bread, soup, meat, and vegetables can be obtained for 100 reis or about 5*d.* On this, however, the institution loses heavily. That it is highly appreciated by the poor is proved by the fact that from 4000 to 6000 meals are served daily at each of the five establishments and this could not be done but for extensive charitable subscriptions.

The bad state of the drainage is undoubtedly one of the causes of the high mortality rate. The sewers are very old and defective and many houses have soil pipes that are neither trapped nor ventilated. These houses therefore become sewer ventilators and, considering that the sewers are the reverse of self-cleansing, it is easy to understand that the sewer air drawn inside the dwelling tends to lower the vitality and to predispose the inhabitants to many dangerous forms of disease. Several vast schemes of drainage have been proposed but they evoke great conflicts of interests and are beset with immense financial difficulties. Thus, though every one is agreed that something must be done, as a matter of fact nothing has been done. To obtain a proper water-supply a concession was given to a private company which has to lay water on in all houses of more than £13 annual rental value and to give a third of its water gratuitously to the city for public purposes, fountains, &c. The water comes in covered conduits directly from the gathering grounds and is considered quite safe and pure, though a little hard. Some 51,000 households are supplied with this water which is sold to them for 8*d.* the cubic metre and they consume on an average 47·5 cubic metres per annum per head. There are also some 3000 wells in Lisbon but it would be dangerous to drink the water which they contain. The police, however, are said to allow such water to be used for garden and washing purposes alone.

Another company, a group of cosmopolitan financiers, has provided Lisbon with a complete network of tramways that run frequently and even in very narrow and steep streets, and there are also elevators or cable cars by which very steep hills can be ascended for a small charge and without any fatigue. For the most part the city is lighted with gas but in some instances electricity is used. Mendicity, the reader will be surprised to hear, is forbidden by law, as also the importuning of pedestrians to buy newspapers, lottery tickets, and various trinkets, but it is acknowledged that these things cannot be prevented so long as there are insufficient places to which these people can be taken and set to some useful work. The problem of the unemployed besets the legislature and the municipalities in Portugal as in many other countries.

If there is here, as in most other places, no efficient means of dealing with the able-bodied pauper, there is no lack of hospitals for the poor and afflicted. The new isolation hospital for the treatment of infectious diseases and, close by, the hospital for tuberculosis are well worth a visit, and I hope on a future occasion to describe in detail what I saw there. Most of the hospitals, however, are not newly constructed. When in 1834 absolutism was abolished in Portugal, many of the convents were suppressed and converted into hospitals. But the hospital of Estaphania for special diseases of women was built some 30 years ago and to it have been added, in the gardens, some pavilions that are especially worth visiting. One of these is built on pillars standing over a concreted basement. The boards that form the floor are not joined together; it is possible to pass a small pencil between each of them, so that fresh air travels upwards throughout the whole of the flooring. The beautiful gardens at the disposal of the convalescent patients, the order and cleanliness, the brightness and light prevailing throughout, will certainly be admired by all visitors, and I hope to describe more fully on another occasion my inspection of this hospital. There are several other important hospitals.

The Bacteriological Institute is by the side of the new medical schools where the Congress meets. It is a recent structure and will not fail to attract many members of the Congress. All the most recent improvements have been introduced here. There are numerous laboratories—some for students, some for the professors, and others for the various forms of work done. Thus there are stoves and heated cupboards for maintaining culture broths at a certain elevated temperature, but there are others for keeping them cool and below the outside temperature, at least during the summer. The preparation of serums is an important department and for this there are some fine stables where donkeys are kept to provide the necessary blood. These animals luxuriate on the best of food and in admirably sanitary stables. They look very sleek and healthy. Of course many other animals are kept on the premises. Of the patients, the most numerous come to be treated for hydrophobia. In 12 years 9547 persons were treated for bites from animals believed to be suffering from rabies. There are also wards for the treatment of children suffering from diphtheria, which is unfortunate, for there is no advantage, and perhaps some risk, in having so infectious a disease in the same building as the bacteriological institute. It is true that elaborate precautions are taken but it would be much preferable to send these children to an isolation fever hospital which is well away from the centre of the town and from other buildings.

The Institute of Hygiene, the School of Tropical Medicine, the Sanitary Department and services at the Ministry of the Interior, the control of the bread- and milk-supply, as well as that of the meat-supply, all are matters of great interest. In regard to milk, it is said that formerly as many as 60 per cent. of samples examined were found to be defective or adulterated. But on August 23rd, 1902, a decree was published by the Minister of the Interior in regard to the collection of samples of alimentary substances and adding to ordinary penalties the posting on the front of the shop an announcement of the verdict pronounced against the shopkeer. As a result, of 100 samples of milk now collected only three or four are found to be defective. There is another excellent law forbidding the sale by pawnshops of second-hand clothes till they have been disinfected and there are such stringent regulations to prevent the spread of tuberculosis that, in many instances, they cannot be applied. Also there are new and improved methods of disinfection and of dealing with passengers, ships, and merchandise coming from ports where plague, yellow fever, or cholera prevails. These are all matters which must be dealt with in detail. For the moment I can only urge that what I have already seen leads to the conclusion that there is something to be learnt from such investigations: and those who choose to profit by the opportunity will not be disappointed with their visit to Lisbon.

THE LATEST NEWS OF THE CONGRESS.

At a late hour this evening the exact number of subscriptions received from members of the Congress was 1451 and for ladies accompanying them 414. As there are thus 1865 names already inscribed it is probable that when the eleventh hour arrivals are included the total figure will exceed 2000. Among those who have arrived is Dr. A. Fernandez Caro, who was general secretary of the Fourteenth International Congress of Medicine held at Madrid three years ago. Also a large number of Brazilian medical practitioners landed to-day It is a great rush to get the new School of Medicine ready for the Congress. Last night, however, the electric light was tried and found to work quite satisfactorily. Never before, I think, will a Congress have met in such absolutely new premises.

The programme of the fêtes is now definitely decided. The inaugural ceremony will take place at 2 P.M. on Thursday, April 19th, and there is to be a reception by Councillor Costa Alemão, President of the Congress. On the next day a garden party will be given by the Visconde Monserrate at Cintra, though how his beautiful grounds are to be reached by many members of the Congress remains a mystery, as at Cintra there are but few carriages available. On April 21st the King will entertain at dinner the official representatives of the various Governments who have been deputed to attend the Congress. On Sunday there will be what is likely to prove the most pleasurable of all the excursions. The members will proceed on a flotilla of steamers on the Tagus to Villa Franca; there they will be entertained at a Portuguese bull-fight, where as is known, every care is taken that bull, horses, and men are not hurt. On Monday afternoon, the 23rd a concert will be given to the ladies at the Zoological Gardens and in the evening there will be a soirée for all the members at the premises of the Geographical Society. Here, Portuguese national songs will be rendered and there will be dissolving views of the principal places of interest in Portugal On the 24th the King will give a garden party to all the members of the Congress at the Palace of Necessidades. In the evening the Government will receive the delegates of the Governments, the schools of medicine, and scientific societies. Finally, on Wednesday, April 25th, the municipality will hold a reception at the town hall. It will be all the easier to profit by these invitations as the sections will not meet in the afternoon but are summoned for the impossible hour of 8.30 in the morning and are expected to continue to sit till 2 or 3 P.M. without any adjournment.

Great disappointment is felt because Professor Behring has announced that he is too ill to attend. His paper on Infectious Diseases among Children will have to be read by someone else. Also the absence of Professor Brouardel will be greatly deplored. He is suffering from pulmonary congestion and is nursing himself at Antibes on the French Riviera.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Birmingham Lying-in Charity.

A YEAR ago the ticket system was abolished in this charity and was replaced by the adoption of a registration fee of half-a-crown. The result has been advantageous to the hospital, for it has received from the fees an additional income of £155 15*s*., whilst the subscription list has remained practically unchanged. The number of cases attended during the year was 1432, or 254 more than in the preceding year and 526 more than the average of the previous ten years. The medical officers were called in 119 times. The experience of the year showed that a further and larger supply of trained and certificated midwives is a necessity. Luckily the hospital is prepared to undertake the training and no other institution in the city can offer advantages equal to those which are associated with this charity. Alderman Cook pointed out that the health committee of the city council had recently investigated the question of the supply of midwives in Birmingham and it was found that of the 221 on the local roll only 21 were certified by examination, 52 could neither read nor write, and many had no conception of the details of that cleanliness which is so essential in the performance of their work. The hospital is not at present large enough for the work which it has to perform and for a time the committee had under consideration the advisability of erecting a new central home in Loveday-street. Plans were prepared but it was found that the scheme was not satisfactory, for the proposed building was too large for the site and sufficient light and air were not obtainable. Fortunately, Mrs. Barrow Cadbury offered the charity a piece of land adjoining the present site. This was a gift of enormous value, for it rendered possible the erection of a satisfactory building provided with sufficient light and air space. The only difficulty which now stands in the way is that of money. The new building will cost about £11,000. The amount at present available is only £7357 and the committee now appeals to the public to provide the remaining £4000. Mr. and Mrs. T. S. Walker have promised £100 contingent upon nine similar gifts and of these four have already been promised. It is unfortunate that this appeal for support, which is so thoroughly well deserved, should have to be made at the same time as the appeal for the Queen's Hospital extension, for the two claims must necessarily clash to a certain extent. Still, it can scarcely be doubted that both will be fully responded to.

The Crippled Children's Union and the Adult Cripples' Guild.

In some respects the institutions the object of which is to aid the crippled should be looked upon as the most deserving of our charities, for though in some cases it is hard to die it is often still harder to live a happy crippled life. I am therefore sorry to hear that the Adult Cripples' Guild will be forced to curtail its efforts unless aid is rapidly forthcoming. It requires monetary aid not only for the continuance of its work but also to wipe out an adverse balance and it requires the assistance of employers of labour who are willing to give a chance of employment to those of its *protégés* who are capable of work. The Adult Guild was formed three years ago, its object being still to keep in touch with the cripples after they leave the Crippled Children's Union at the age of 16 years. It is to be hoped that the necessary help will be forthcoming, for it is obvious that to cast the cripples adrift at 16 years of age after taking care of them, first in a special school and then in the Crippled Children's Union, is an act of sheer cruelty, for the care previously bestowed upon them will only have enabled them to feel more acutely their subsequent distress. During the past year 180 cases have been on the register of the Adult Guild—that is, 20 more than in the previous year. Through the generosity of Mrs. Barrow Cadbury, who lent the Guild a cottage at Blackwell for three months, 28 members were sent away for a holiday, with very beneficial results. At present there are about 20 cases capable of work and unable to obtain it, and it is for these especially that the committee appeals to the employers of labour.

The Royal Orthopædic Hospital.

The new out-patient department of the Orthopædic Hospital has been commenced and when completed it will greatly facilitate the work of the hospital but will not provide everything which is required, for the old hospital must be rebuilt. The committee recognises the necessity for rebuilding, or at all events for considerable alterations and extensions but it sees that the present moment is not an opportune one for an appeal to the public, more especially as it does not wish in any way to interfere with the claims of the Queen's Hospital extension appeals. The hospital was founded in a very small way nearly 90 years ago and it is 40 years since it was transferred to its present site. The work has gradually outgrown the capabilities of the building and a few years ago it became essential to acquire temporary premises for the out-patient work. The premises obtained were hired from the corporation and are now required in connexion with the Council House Extension Scheme. Therefore, of necessity, a new out-patient department had to be erected and ground was acquired on favourable terms from the Colmore trustees. When the building is completed it will have a frontage of 22 feet in Great Charles-street and will extend back for 85 feet, and when the old hospital is rebuilt it will be separated from the new out-patient department only by a garden which will be common to the two buildings. On the ground floor in the new out-patient department there will be an out patients' waiting room large enough to accommodate 85 people, a surgeons' room, dressing rooms, and a dispensary. On the first floor will be exercising rooms and massage rooms for males and females; nurses' rooms, an isolation room, and the bathrooms will be on the second floor. Accommodation for perambulators will be provided in the basement. The foundation-stone of the new department was laid by the Lord Mayor (Councillor A. J. Reynolds) and the ceremony was presided over by the Marquis of Hertford.

Bequests to Local Charities.

Under the will of the late Mrs. Mary Day of Worcester the Worcester Infirmary receives £2000, the Royal Albert Orphan Asylum £500, and the Birmingham Blind Institution £500.—The late Mr. George Martin of Birmingham has bequeathed £100 to each of the following institutions: the General Hospital, the Queen's Hospital, the Midland Eye Hospital, and the General Institution for the Blind.

Police Ambulance.

The recent competition for the Rowland Mason Challenge Cup demonstrated in a very pleasant way the admirable efficiency of the training of the members of our police force in association with ambulance work. The men were keen and active; they knew what was required and how to do it. In the competition they were required not only to treat ordinary accidents but also to rescue insensible persons from a room filled with gas and to extricate others entangled in "live" electric wires and to give efficient first aid to each set of sufferers. The chairman of the watch committee (Mr. Godlee) pointed out that the police gave assistance in about 1000 accidents during the year, therefore it is essential that they should be well trained in ambulance work, and there can be no doubt that competitions such as that for the Rowland Mason Challenge Cup act as useful stimuli.

April 17th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester and Salford Sanitary Association.

THE annual meeting of the Manchester and Salford Sanitary Association was held in the town-hall on March 29th. The report showed a continuance of the steady work in aid of more healthful conditions which has characterised this useful institution. Among other things, an investigation is being carried on as to the possibility of further safeguards for the workers in the manufacture or use of white lead; into the cause of lamp explosions, an inquiry which has brought a diminution of such explosions; into the overcrowding of tramcars, the objectionable and unhealthy character of third-class smoking carriages, &c. Pressure is brought to bear on the city council to extend the provision of cottage baths and washhouses in the poorer parts of the city. It is one of the most civilising and health-saving directions in which the council can expend the ratepayers' money. But baths and washhouses for the poor are hidden away in mean streets; there is no great beauty about them, no architectural splendour or glamour of decoration, no great cost, which latter makes the heart of the average town councillor throb with pride, for he likes to see something that is "an ornament to the city," even if poor women and children have to go unwashed. Even the Local Government Board seems sometimes to be startled at the magnificent borrowings of the corporation. The sum now wanted is £39,715 for new baths and washhouses at Bradford, a working-class suburb. It certainly is a district where public baths and washhouses are needed, for it is said that out of 11,949 dwelling-houses there are only 411 with baths. Swimming-baths, of course, require space and those who want a swim should not begrudge a walk for it, as they cannot be scattered broadcast, but it is quite a different thing for a poor woman with her bundle of soiled clothing and two or three little children who want washing. These conveniences should be near the homes of the people.

Placarding Alcohol.

One of the attractions at the meeting of the Sanitary Association was the presence of Professor G. Sims Woodhead who gave an address on the relationship of alcohol to nutrition. He spoke of the former as lowering the action of the various tissues and organs of the body, of how it blunted the sensations, and among them those of hunger and fatigue, and ended his discourse by saying that the only disease from which teetotalers died more frequently than moderate drinkers was old age. To show, however, that this teaching is not universally received, one need only go as far as Warrington where recently at a meeting of the town council one of the members protested against the issuing of a placard calling attention to the evil effect of the abuse of alcohol on public health. "Alcohol was all right," he said, "if taken regularly," and he drew attention to the opinion of a medical man that it was the best thing in the world for killing microbes. One cannot pretend that the scientific standard of the Warrington town council is very lofty, but when the mayor stated that the people for whom it was meant would be too drunk to see the placard a ray of common sense illumined the mind of an alderman who said that was the best reason for its publication, for those who could read it might tell the others. The placard was founded on the Birmingham model and on the recommendation of the Committee on Physical Deterioration. After all the discussion it was decided to publish the placard.

A New Ear Hospital.

The Manchester Ear Hospital was founded in 1855 by a few gentlemen who were anxious that there should be some better provision for the treatment of diseases of the ear than at that time existed in Manchester. Sir James Bardsley, M.D., was the first president. Four rooms in Oxford-street were occupied for the Ear Institution, as it was then called, had very modest beginnings. In 1867 there was a change of quarters to Lower Mosley-street and in 1870 the first grant of £36 was received from the Hospital Sunday Fund. Another change, to 25, Byrom-street, was made in 1877 and there it remained till 1884 when it moved to its present quarters at 23, Byrom-street. The desirability of providing for in-patients was urged by the medical staff for years and the department was established in 1893. During the following year 60 in-patients were received and the number has gradually increased till in 1904–05 271 were admitted. The honorary staff consists of a consulting physician, Dr. H. Simpson; Dr. F. M. Pierce, consulting surgeon; four surgeons, Mr. T. H. Pinder, Dr. F. Cox, Dr. W. Milligan, and Dr. L. Larmuth, while Dr. Herbert Lund is the anæsthetist. The work has steadily increased year by year and has "outgrown the capacity of the existing hospital in Byrom-street." The board of management has long had the question of removal under consideration and has now taken preliminary measures by securing the option of purchasing, at a reasonable price, a piece of land near the new Infirmary in Oxford-road which, by the way, will soon become the principal hospital quarter of Manchester. The scheme is to provide at first 24 beds for in-patients and the building will be so arranged as to allow of enlargement when required. An appeal therefore is made for £15,000, which will cover, it is believed, the cost of the land and the erection of the building, and this public appeal, the first in the history of the hospital that has extended beyond the limited circle of the annual subscribers, may well include a wider public than that of Manchester, for, as a matter of fact, the patients come from all parts of Lancashire and Cheshire, while some hail from Yorkshire, Derbyshire, and others of the northern counties. When the hospital is established in Oxford-road it will be more easily available to the students than at present and no doubt some arrangements as to the teaching of the somewhat neglected subject of ear disease will be made and the clinical material will be more thoroughly utilised.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Spread of Sleeping Sickness in Africa: Address by Dr. J. L. Todd.

AT a meeting of the African trade section of the Liverpool Chamber of Commerce Dr. J. L Todd delivered an address on the Danger of the Spread of Sleeping Sickness throughout Africa and the Necessary Measures for its Prevention. Dr. Todd illustrated his lecture by means of maps shown on a screen. He remarked that the distribution of sleeping sickness was probably more universal than was indicated, since the disease was not infrequently present without its nature being recognised. The name of the malady was misleading. It was called sleeping sickness but, as a matter of fact, sleep was far from an important symptom and occurred only in the terminal stage of the disease in a small number of cases. Isolated cases had occasionally been reported from Sierra Leone but in a general way sleeping sickness was said not to exist in Freetown. Captain Grant, R.A.M.C., by employing a perfected means of diagnosis had shown that it occurred there more frequently than had been thought. He had had between 16 and 20 cases under his care during the past few months. A few of these were imported cases and the remainder were natives who had never been out of the colony. Injurious epidemics of sleeping sickness had occurred in the neighbourhood of Sierra Leone. For instance, the region just south of the Gambia, about the Cosamance river, had suffered severely. In view of this fact, they must at least consider the danger of such epidemics making their appearance in Sierra Leone. It was practically impossible to collect trustworthy statistics of sickness and death among the shifting African native populations, and although sleeping sickness was so prevalent it was extremely difficult to make an intelligent estimation of the number of persons who had died from it. He thought, however, that it would not be far from the truth to state that from 400,000 to 500,000 natives had died from this cause in Africa during the past ten years. The fact that the disease was so widespread in Africa was sufficiently disconcerting. What was more alarming was the rapidity with which it was spreading. To indicate this point Dr. Todd took as an example that part of Africa which was worked over by the expedition sent out by the Liverpool School of Tropical Medicine to study sleeping sickness in 1903. He referred to the Congo Free State. It was a large dominion; it covered an area equal to one-third of the United States and therefore conditions found to exist there might safely be used in making generalisations. By means of circles on a map Dr. Todd indicated posts administered by white men in which the first recognised cases of sleeping sickness occurred amongst individuals—soldiers, labourers, and their wives—imported into the district by white men. The history of the spread of the disease in the Congo indicated that each of these posts might become in its turn a centre of infection for the surrounding district. Having pointed out that districts in the Congo and Uganda had been made desolate through the disease, he said that the weight of opinion at the moment was that no person once infected ever recovered. Surely an attempt should be made to protect districts not yet infected. Yet nothing was at present being done by the Colonial Government to protect the natives in British Central Africa from their imminent danger. To arrest, for a time at least, the spread of the disease it was proposed to prevent infected persons from entering non-infected districts. It was easy enough to recognise the person who was infected, for, as a general rule, an enlargement of the glands of the neck without obvious cause in Africans might be taken as a sign of sleeping sickness As a means of combating the disease it was recommended that medical posts of inspection along the most travelled trade routes should be established; and, secondly, the transportation of infected persons at present living in uninfected districts to localities already infected. The application of these measures would be obtained by informing every employer of labour of the significance of enlarged cervical glands. Each of them would be trusted to examine his staff and to send suspected persons towards infected regions to the nearest medical man, where, if it was necessary for diagnosis, the patient would be watched. Dr. Todd concluded his address by emphasising that the enormous spread and great increase of sleeping sickness in the Congo basin during recent years had been in a great measure due to the increase in travel, following the opening up of the country; that cases of trypanosomiasis, though apparently healthy, might be detected by their enlarged glands; and that good results might be expected from the serious application of quarantine measures dependent for their efficiency upon cervical gland palpation. Sir Alfred Jones subsequently entertained the members of the section, including Dr. Todd, to luncheon at the North-Western Hotel.

The Select Vestry and the late Dr. Arthur Blackwood.

MR. William Crosfield, at a meeting of the select vestry held on April 9th, took the opportunity to pay a tribute to the late Dr. Arthur Blackwood whose loss the vestry mourned in common with the widow. Dr. Blackwood's tenure as a medical officer at the Liverpool workhouse covered the period May, 1885, to July, 1889. He had had a career of singularly brilliant promise narrowed by poisoning which he incurred by devotion to duty. For months his life hung in the balance and on partial recovery he was appointed public vaccinator, in which office he gave valuable service until the end. Other members reciprocated Mr. Crosfield's sentiments.

The New Hospital at Fazakerley.

NO inconsiderable interest centres in the opening of the palatial city infectious diseases hospital at Fazakerley which will take place on April 25th. This fine institution has cost the ratepayers of Liverpool a large sum of money and it is claimed that it is one of the finest hospitals of its kind in the kingdom. Mr. J. Utting, the chairman of the port sanitary and hospitals committee, will perform the inaugural ceremony.

April 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Universities Carnegie Trust: Alterations regarding Class Fees.

IN the last report of the executive committee of the Carnegie Trust for the Scottish Universities it was intimated that the regulations as to the payment of class fees would require to be reconsidered because of the demands which had been made upon this department of the trust. The changes determined on have now been published and in so far as they bear upon the Faculty of Medicine they are as follows. Under "degree examinations" it is provided that if a student has failed on two occasions to pass an examination no further fees are to be paid until he has passed. Under "advanced and honours classes" it is provided that the payment of class fees is to be confined to the class attendances required for a curriculum for an ordinary degree. This rule, it may be mentioned, was necessary because of the great number of extra classes which students were taking out and getting the trust to pay the fees. The rule, however, carries an important concession with it—namely, that in the case of students who have already passed the ordinary examination for graduation in the relative subject payment may be made of the fees of the past year 180 cases have been on the register of the Adult Guild—that is, 20 more than in the previous year. Through the generosity of Mrs. Barrow Cadbury, who lent the Guild a cottage at Blackwell for three months, 28 members were sent away for a holiday, with very beneficial results. At present there are about 20 cases capable of work and unable to obtain it, and it is for these especially that the committee appeals to the employers of labour.

The Royal Orthopædic Hospital.

The new out-patient department of the Orthopædic Hospital has been commenced and when completed it will greatly facilitate the work of the hospital but will not provide everything which is required, for the old hospital must be rebuilt. The committee recognises the necessity for rebuilding, or at all events for considerable alterations and extensions but it sees that the present moment is not an opportune one for an appeal to the public, more especially as it does not wish in any way to interfere with the claims of the Queen's Hospital extension appeals. The hospital was founded in a very small way nearly 90 years ago and it is 40 years since it was transferred to its present site. The work has gradually outgrown the capabilities of the building and a few years ago it became essential to acquire temporary premises for the out-patient work. The premises obtained were hired from the corporation and are now required in connexion with the Council House Extension Scheme. Therefore, of necessity, a new out-patient department had to be erected and ground was acquired on favourable terms from the Colmore trustees. When the building is completed it will have a frontage of 22 feet in Great Charles-street and will extend back for 85 feet, and when the old hospital is rebuilt it will be separated from the new out-patient department only by a garden which will be common to the two buildings. On the ground floor in the new out-patient department there will be an out patients' waiting room large enough to accommodate 85 people, a surgeons' room, dressing rooms, and a dispensary. On the first floor will be exercising rooms and massage rooms for males and females; nurses' rooms, an isolation room, and the bath-rooms will be on the second floor. Accommodation for perambulators will be provided in the basement. The foundation-stone of the new department was laid by the Lord Mayor (Councillor A. J. Reynolds) and the ceremony was presided over by the Marquis of Hertford.

Bequests to Local Charities.

Under the will of the late Mrs. Mary Day of Worcester the Worcester Infirmary receives £2000, the Royal Albert Orphan Asylum £500, and the Birmingham Blind Institution £500.—The late Mr. George Martin of Birmingham has bequeathed £100 to each of the following institutions: the General Hospital, the Queen's Hospital, the Midland Eye Hospital, and the General Institution for the Blind.

Police Ambulance.

The recent competition for the Rowland Mason Challenge Cup demonstrated in a very pleasant way the admirable efficiency of the training of the members of our police force in association with ambulance work. The men were keen and active; they knew what was required and how to do it. In the competition they were required not only to treat ordinary accidents but also to rescue insensible persons from a room filled with gas and to extricate others entangled in "live" electric wires and to give efficient first aid to each set of sufferers. The Spread of Sleeping Sickness in Africa: Address by Dr. J. L. Todd.

AT a meeting of the African trade section of the Liverpool Chamber of Commerce Dr. J. L Todd delivered an address on the Danger of the Spread of Sleeping Sickness throughout Africa and the Necessary Measures for its Prevention. Dr. Todd illustrated his lecture by means of maps shown on a screen. He remarked that the distribution of sleeping sickness was probably more universal than was indicated, since the disease was not infrequently present without its nature being recognised. The name of the malady was misleading. It was called sleeping sickness but, as a matter of fact, sleep was far from an important symptom and occurred only in the terminal stage of the disease in a small number of cases. Isolated cases had occasionally been reported from Sierra Leone but in a general way sleeping sickness was said not to exist in Freetown. Captain Grant, R.A.M.C., by employing a perfected means of diagnosis had shown that it occurred there more frequently than had been thought. He had had between 16 and 20 cases under his care during the past few months. A few of these were imported cases and the remainder were natives who had never been out of the colony. Injurious epidemics of sleeping sickness had occurred in the neighbourhood of Sierra Leone. For instance, the region just south of the Gambia, about the Cosamance river, had suffered severely. In view of this fact, they must at least consider the danger of such epidemics making their appearance in Sierra Leone. It was practically impossible to collect trustworthy statistics of sickness and death among the shifting African native populations, and although sleeping sickness was so prevalent it was extremely difficult to make an intelligent estimation of the number of persons who had died from it. He thought, however, that it would not be far from the truth to state that from 400,000 to 500,000 natives had died from this cause in Africa during the past ten years. The fact that the disease was so widespread in Africa was sufficiently disconcerting. What was more alarming was the rapidity with which it was spreading. To indicate this point Dr. Todd took as an example that part of Africa which was worked over by the expedition sent out by the Liverpool School of Tropical Medicine to study sleeping sickness in 1903. He referred to the Congo Free State. It was a large dominion; it covered an area equal to one-third of the United States and therefore conditions found to exist there might safely be used in making generalisations. By means of circles on a map Dr. Todd indicated posts administered by white men in which the first recognised cases of sleeping sickness occurred amongst individuals—soldiers, labourers, and their wives—imported into the district by white men. The history of the spread of the disease in the Congo indicated that each of these posts might become in its turn a centre of infection for the surrounding district. Having pointed out that districts in the Congo and Uganda had been made desolate through the disease, he said that the weight of opinion at the moment was that no person once infected ever recovered. Surely an attempt should be made to protect districts not yet infected. Yet nothing was at present being done by the Colonial Government to protect the natives in British Central Africa from their imminent danger. To arrest, for a time at least, the spread of the disease it was proposed to prevent infected persons from entering non-infected districts. It was easy enough to recognise the person who was infected, for, as a general rule, an enlargement of the glands of the neck without obvious cause in Africans might be taken as a sign of sleeping sickness. As a means of combating the disease it was recommended that medical posts of inspection along the most travelled trade routes should be established; and, secondly, the transportation of infected persons at present living in uninfected districts to localities already infected. The application of these measures would be obtained by informing every employer of labour of the significance of enlarged cervical glands. Each of them would be trusted to examine his staff and to send suspected persons towards infected regions to the nearest medical man, where, if it was necessary for diagnosis, the patient would be watched. Dr. Todd concluded his address by emphasising that the enormous spread and great increase of sleeping sickness in the Congo basin during recent years had been in a great measure due to the increase in travel, following the opening up of the country; that cases of trypanosomiasis, though apparently healthy, might be detected by their enlarged glands; and that good results might be expected from the serious application of quarantine measures dependent for their efficiency upon cervical gland palpation. Sir Alfred Jones subsequently entertained the members of the section, including Dr. Todd, to luncheon at the North-Western Hotel.

The Select Vestry and the late Dr. Arthur Blackwood.

Mr. William Crosfield, at a meeting of the select vestry held on April 9th, took the opportunity to pay a tribute to the late Dr Arthur Blackwood whose loss the vestry mourned in common with the widow. Dr. Blackwood's tenure as a medical officer at the Liverpool workhouse covered the period May, 1885, to July, 1889. He had had a career of singularly brilliant promise narrowed by poisoning which he incurred by devotion to duty. For months his life hung in the balance and on partial recovery he was appointed public vaccinator, in which office he gave valuable service until the end. Other members reciprocated Mr. Crosfield's sentiments.

The New Hospital at Fazakerley.

No inconsiderable interest centres in the opening of the palatial city infectious diseases hospital at Fazakerley which will take place on April 25th. This fine institution has cost the ratepayers of Liverpool a large sum of money and it is claimed that it is one of the finest hospitals of its kind in the kingdom. Mr J. Utting, the chairman of the port sanitary and hospitals committee, will perform the inaugural ceremony.

April 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Universities Carnegie Trust: Alterations regarding Class Fees.

IN the last report of the executive committee of the Carnegie Trust for the Scottish Universities it was intimated that the regulations as to the payment of class fees would require to be reconsidered because of the demands which had been made upon this department of the trust. The changes determined on have now been published and in so far as they bear upon the Faculty of Medicine they are as follows. Under "degree examinations" it is provided that if a student has failed on two occasions to pass an examination no further fees are to be paid until he has passed. Under "advanced and honours classes" it is provided that the payment of class fees is to be confined to the class attendances required for a curriculum for an ordinary degree. This rule, it may be mentioned, was necessary because of the great number of extra classes which students were taking out and getting the trust to pay the fees. The rule, however, carries an important concession with it—namely, that in the case of students who have already passed the ordinary examination for graduation in the relative subject payment may be made of the fees of honours classes or of classes dealing with a distinct extension of the range of work belonging to the obligatory classes. Special application forms for fees of such classes have to be applied for. With regard to attendances in more than one faculty at a time, this will not be allowed unless a satisfactory reason is given. A beneficiary comes under an obligation to refund the fee of any class in which he has failed to obtain a certificate that he has given regular attendance and duly performed the work of the class during the session. No payment will be made of fees of classes in which such certificates are not issued by the teacher. There are classes held in the summer where no qualifying work is demanded and therefore no qualifying certificate is given. It is felt that the trust cannot continue to pay fees without a guarantee. These alterations will have a salutary check upon the marked tendency which the Carnegie money has had in increasing the number of extra classes and in encouraging students to take out such classes from quite insufficient reasons. It is interesting to note the adaptability of the Carnegie Trust to circumstances as they evolve, whilst the universities seem to be tied hand and foot by regulations or ordinances that nothing short of an earthquake seems capable of moving.

University of Edinburgh: Spring Graduation.

At the spring graduation ceremonial at the University of Edinburgh on April 12th the following amongst others received the degree of Doctor of Laws (LL.D.): His Grace the Duke of Bedford; Dr. Alexander Graham Bell, the inventor of the telephone and a native of Edinburgh; His Excellency Wirklicher Geheimrat, Dr. Ernst von Bergmann, professor of surgery and director of the Royal Surgical Clinique in the University of Berlin; Dr. David Christison, son of Sir Robert Christison, and known for his archæological attainments; Professor George Dancer Thane, of University College, London; Mr. A. Taylor Innes, Mr. William Crawthorne Unwin, F.R.S., and Miss Louisa Stevenson.

The Smoke Nuisance.

The smoke problem is asserting itself even in Edinburgh and any light on the solution of it is to be welcomed. Mr. G. H. Gemmell has been reading a paper before the Edinburgh Association of Science and Arts on Coal and What We Get from It, and in the course of his paper he gave facts which have an important bearing on this subject. He said that the ideal system of utilising the energy in coal was to convert it into gas at the pit's mouth and to convey it in pipes to the consumers for direct use in gas engines. All cooking and heating would be done by gas, soot and smoke would disappear, and the tons of sulphuric acid and soot which were discharged into the air would be saved for useful purposes. The value of sulphate of ammonia recovered in gasworks was worth £2,500,000 sterling, while if the ammonia from all the coal consumed was saved it would have a value of £36,000,000. The ideal does not appear to be impracticable and the amount of cleaning that would be saved would be enormous. Electricity for lighting and gas for heating, cooking, and driving machinery would make our cities and our houses clean.

Glasgow Royal Infirmary: Post-Graduate Classes.

The winter term has proved a very successful one, the attendance being highly satisfactory. The course embraced 11 subjects and all the classes were conducted on strictly practical lines so that those who attended had every opportunity of becoming familiar with the various conditions demonstrated. The summer term will begin on April 30th and will include demonstrations on Neuro-Pathology, by Dr. Walter K. Hunter; Gynæcology, by Dr. James K. Kelly and Dr. G. Balfour Marshall; Diseases of the Throat and Nose, by Dr. Robert Fullerton; Clinical Medicine, by Dr. George S. Middleton and Dr. James W. Allan; Clinical Surgery, by Mr. J. Hogarth Pringle and Dr. Peter Paterson; Bacteriology, by Mr. David McCrorie; and Operative Surgery, by Mr. Henry E. Clark.

Beri-beri in the Clyde.

For the second time within the last three months a steamer has arrived in the Clyde with cases of beri-beri on board. In this instance the steamer hailed from Rangoon and the two patients, who were members of the lascar crew, have been removed to Belvidere Hospital.

Death of a Retired Moffat Medical Man.

The death at his residence, Vicarlands, Moffat, is announced of Dr. James Munro, a retired medical practitioner who for over half a century has been one of the most respected and prominent townsmen of Moffat The deceased, who was 80 years of age, was a native of Musselburgh and for 44 years was the leading member of the medical profession in Moffat where he built up a very extensive practice from which he retired 13 years ago. Dr. Munro in 1847 was one of the medical men who was sent to Dumfries to combat the cholera plague in that town.

Munificent Gift for Ross shire.

Seaforth, the chief of the Mackenzies, and Mrs. Stewart Mackenzie of Brahan Castle, have intimated their intention of building, equipping, maintaining, and ultimately endowing a consumption sanatorium in Ross-shire. The object of the sanatorium will be to submit early cases of pulmonary tuberculosis for several months to treatment with a view to arrest the progress of the disease and to effect a cure, and also to educate the patients in the system of open-air treatment so that on leaving they may introduce the principles to their own homes which will become centres of instruction to others. The sanatorium will be open to the inhabitants of Ross and Cromarty, and no charge will be made for the treatment. The site will be on the Brahan estate and the building will be modelled on the type of the one erected by the Brompton Hospital for Consumption at Frimley in Surrey.

April 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Trinity College Commission.

ALL questions about medical matters seem to have given place in Dublin to the discussions and letters which appear daily with reference to the forthcoming commission of inquiry about the affairs of Trinity College. Mr. Bryce's statement in the London *Times* of March 21st satisfied most moderate people, for in it he pointed to the fact that since the last commission on Trinity College there has been a complete revolution in English university life—four commissions of inquiry into the Universities of Oxford and Cambridge and three commissions as regards the universities of Scotland, and that as a result much progress had been made. How Trinity College escaped those commissions of inquiry is not mentioned and the fact leaves an opening to Nationalist Members of Parliament, who will doubtless be very ready to use it. They may fairly ask, Why is it that this college, if it proposes to be a national college, has not a single Roman Catholic on its governing board? and Why are the fees for medical graduates far higher—in this poor country—than those charged in Edinburgh and in Glasgow? There are many other matters that Mr. Bryce's commission should deal with. I trust that it will. As to the attacks on the examinations they seem of no importance.

National Association for the Prevention of Tuberculosis.

The fifth general meeting in connexion with the Dublin branch of the National Association for the Prevention of Tuberculosis was held on April 10th in the Mansion House, Mr. Field, M.P., occupying the chair. Sir Thornley Stoker, President of the Royal Academy of Medicine, in moving the adoption of the report, paid a high tribute to the admirably careful analysis of the death-rate recently issued by the Registrar-General.

The Royal University of Ireland.

Dr. Edward Magennis of Dublin has issued his address as a candidate for the senatorship of the Royal University. He appeals to the electors as a graduate of 20 years' standing and as one who, from the fact that he resides in Dublin, will be able to attend the meetings. He believes that graduates should have full access to the University buildings and grounds. He gives in connexion with the Royal University the following interesting figures: Salaries of Fellows, £8790; remuneration of examiners, £3048; travelling expenses of examiners, £1741; exhibitions, £2414; studentships, £1450; and junior Fellows, £1550; leaving a balance of £12,893, a part of which Dr. Magennis thinks should be applied in developing the utility and resources of the library so that graduates and students could make use of it, while part, he considers, should be given in additional exhibitions and prizes. The election is to take place on April 20th.

Belfast Ophthalmic Institution.

At the annual meeting of the supporters of this hospital held on April 9th it was reported that there were 1518 new extern eye cases and 695 ear and throat patients in 1905, while the intern cases numbered 122, making a total of 2235 patients seen during the year. In the wards there were 103 operations. Financially the year began with a debit balance of £96 and terminated with a sum of £200 on the wrong side of the account. Dr. Cecil E. Shaw read the medical report. Dr. J. Walton Browne said that in his opinon a large number of people in Belfast who were able to pay for medical attendance should not be received into any of the larger charities; they should go into some of the well-equipped private hospitals in the city. Dr. V. G. L. Fielden was thanked for his services as anæsthetist and Professor W. St. Clair Symmers was appointed pathologist to the hospital.

The Consumption Problem in Belfast.

The chairman of the Belfast public health committee having stated at the last public meeting of the city council that any suggestions would be welcomed for improving the health of the city or lessening the death-rate, Professor J. W. Byers has in a published article proposed the adoption in Belfast of the recommendations made in the memorandum recently issued by the Scotch Local Government Board. Professor Byers produces figures to show that when Belfast is contrasted with other cities (such as Manchester, Liverpool, Northampton, Blackburn, Salford, Oldham, Halifax, Brighton, Glasgow, Aberdeen, Dundee, Leith, Paisley, and Greenock) it appears that the death-rate in them from consumption has steadily fallen, while in Belfast for the past 12 years the average death-rate from the same disease has kept at 3·3 per 1000, a ratio immensely higher than in the great English and Scotch cities. Again, while the death-rate from pulmonary tuberculosis in Belfast in 1894 was 3·5, it was last year (1905) 3·1. That is, statistics demonstrate that the death-rate from pulmonary tuberculosis in Belfast was much too high and showed little, if any, sign of falling. In the decennial report (1891–1900) for Ireland the highest death-rate from pulmonary tuberculosis for any of the civic unions was 35·0 per 10,000 in South Dublin union; in Belfast it was 34·1, in Cork 33·6, and in Dublin North 32·1. The rate for the two unions, Dublin North and Dublin South combined, was 33·8—that is, less than in Belfast. During this same ten years no less than 73,349 persons (35,147 males and 38,202 females) succumbed in Ireland to pulmonary tuberculosis between the ages of 15 and 45 years. In Scotland between the periods 1861–65 and 1901–02, the death-rate from pulmonary tuberculosis has fallen 42 per cent., in England between 1861–65 and 1901–03 it has steadily declined 52 per cent , while in Ireland between 1864–65 and 1901–03 it has actually increased 20 per cent. It is to be hoped that the public health authorities will take some real action in Belfast towards stamping out consumption, the death-rate from which in that city is appalling.

Post-Graduate Classes in Belfast.

During the ensuing summer a post-graduate course of practical demonstrations of cases and clinical methods is to be given between July 16th and 28th by the medical staff of the Royal Victoria Hospital, Belfast, at that institution.

Death of Mr. Joseph Graham Burne.

Mr. J. Graham Burne, L.R.C.P. Irel., M.R.C.S. Eng , a well-known medical practitioner of Dublin, died on April 16th at his residence, 38, Westland-row. He was in his sixty-third year, and in addition to being one of the medical officers of the South Dublin union was for many years physician to the City of Dublin prisons. He was much esteemed in the city.

April 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Interesting Results obtained by Hypnotic Suggestion.

AT a meeting of the Society of Hypnology and Psychology held on Feb. 20th two members related the following interesting cases. The first, an account of which was given by M. Damoglou, related to a woman, aged 29 years, who suffered from frequent convulsive crises brought on by any mental disturbance. Some four years ago she completely lost the power of speech, but at the end of 15 days, thanks to hypnotic suggestion, she was able to speak as well as ever. Some months ago, after a convulsive crisis, she again lost the power of speech. M. Damoglou hypnotised her, and while she was in the hypnotic sleep he made her take a placebo (*médicament psychique*), to which the suggestive influence of M. Damoglou added a powerful therapeutical effect. When the woman woke up from her hypnotic trance she could speak perfectly well. The second case was described by Dr. Bonjour and related to the lying-in room. A certain number of cases which had come under his charge had enabled him to conclude that in cases where he was able to put the woman into a state of hypnotism she would be confined on a suggested day on condition that this day was not sooner than eight days before the expected date of her confinement as calculated by the ordinary method and after examination of the patient. He said that the physician who adopted this method of treatment ought not to leave the patient before dilatation of the os had commenced. If, however, the physician could not spare the time for this or if he could not manage to bring about the state of hypnotism he could, however, without being definitely sure of bringing on labour on the suggested day cause that it should commence during the night and that the period of dilatation and expulsion should not take place until the next day.

Abscess of the Breast treated by Iodoacetone.

At a meeting of the Therapeutical Society held on March 28th M. Camescasse stated that M. Danlos by the introduction of iodoacetone had done a great service to the country medical man. Iodoacetone renders superficial inflammatory processes aseptic and even if applied too late to prevent the formation of pus it liquefies the pus and makes the abscess a collection of harmless matter which may be easily evacuated, while the wound heals up very readily. If the abscess occurs in a portion of the body provided with natural evacuant channels, even though such be merely capillary, the medical man need not incise it, for the pus is rendered so liquid that it escapes by the natural channels. Hence, in abscess of the breast all that is necessary is to brush iodoacetone over the gland as long as the breast has not been converted into a mere bag of pus holding skin. However red or hot or swollen the breast may be treatment should begin by brushing it over with iodoacetone. If the abscess is pointing it may be incised at any time, from half an hour afterwards to the following day. But in any case two hours after the application of the iodoacetone a breast-pump should be applied, when the surgeon will easily be able to draw off without any pain a mixture of milk, pus, and serous fluid. The skin will become wrinkled but after 48 hours the breast will have regained its normal consistency. M. Camescasse tried this method with perfect success in the case of a very timid patient who refused any surgical intervention. He has, moreover, met with success in many similar cases.

Hernia of the Appendix in the Sac of a Femoral Hernia.

At a meeting of the Surgical Society held on March 28th Dr. le Clerc gave an account of a case of femoral hernia in a woman, aged 62 years. Two years previously she had noted a swelling in the right groin, which, however, disappeared spontaneously. When Dr. le Clerc saw her she had no rise of temperature but marked signs of abdominal mischief (*péritonisme*); for some days previously she had suffered from diarrhœa and tenesmus. The swelling in the groin was dull to percussion, hard, as thick as a thumb, and about five centimetres long. Dr. le Clerc opened the sac and found within the appendix and its mesentery. The tip of the appendix was ulcerated but not gangrenous. The hernia was therefore complicated with a masked appendicitis, to which was due the diarrhœa. Dr. le Clerc compared this case with a similar one under the care of M. Moty and mentioned that in his opinion the elongated form of the hernia and its firm consistence were typical of an isolated hernia of the appendix.

The Surgical Treatment of Eclampsia.

At a meeting of the Academy of Medicine held on April 3rd M. Chamberland and M. Pousson communicated a paper upon the Surgical Treatment of Eclampsia by means of Nephrotomy. This treatment, which was introduced in America by Edebohls, has been adopted frequently since in France. In eclampsia there almost always coexist nephritis and albuminuria. The kidney substance accordingly swells and becomes too large for its fibrous capsule. It is not certain that this is the cause of the nephritis and the albuminuria but it is certain that Edebohls, who was ingenious and bold enough to lay bare the kidney and to incise its capsule, saw the kidney herniate through the capsular wound and, moreover, noted that with the decompression of the kidney the eclampsia disappeared. The operation has frequently been performed in various hospitals with results which could hardly have been hoped for. It is, however, undoubtedly a serious thing to cut down on to and to incise the kidney in every pregnant woman who shows signs of eclampsia. A milk diet, bleeding, and intravenous injections, together with lumbar puncture, seem to give as good results as incision of the kidney without the risks attaching to the latter operation.

The Treatment of Congenital Syndactyly.

At a meeting of the Society of Surgery held on April 4th M. Quénu showed a child the subject of congenital syndactyly of several fingers in either hand. In this case M. Quénu had tried various methods of plastic operation for the cure of the condition. He tried the method of Zeller and the method of Didot and the Italian method which consists in taking a flap from the skin of the abdomen. In M. Quénu's opinion this last method as a rule is that which gives the best results.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Roentgen Rays in Military Surgery.

Dr. Colmer, a surgeon to the German Red Cross Hospital with the Russian forces in Manchuria, writing to the *Münchener Medicinische Wochenschrift*, describes his experiences of radiography in the Russo-Japanese war. He discusses the question where the Roentgen ray apparatus should be placed and what pattern of apparatus is best fitted for use in war. He believes that radiographic apparatus is out of place both in the dressing stations on the battlefield and also in the moveable field hospitals and that it ought to be reserved for the stationary and base hospitals. He says that the employment of radiography is practically impossible on the battlefield and extremely difficult in a moveable field hospital. Radiographic examination in military surgery is used principally to ascertain whether a projectile remains in the body and whether it requires removal. Dr. Colmer explained that a bullet, as a rule, is not to be removed at once but only either when the wound has become contaminated or when the bullet causes severe pains or nervous troubles by pressure on bones or nerves. These effects, however, occur only after the lapse of a period which permits the conveyance of the patient to a stationary hospital. The same is the case in complicated fractures of the bones where the Roentgen rays are useful for an accurate coaptation of the fragments—a work which is undertaken in the stationary hospitals and not on the battlefield or in the moveable field hospitals. According to his experiences in Manchuria there was no case where an immediate radio graphic examination was required in a field hospital. In conclusion he gives some hints relative to the fitting-up of the Roentgen ray room in military hospitals.

The German Congress on Radiography.

The German Roentgen Society was founded in 1905 and held its second meeting on April 2nd in Langenbeck House, Berlin, Professor Eberlein being in the chair. The meeting was attended by about 350 members, including medical and scientific men from Germany and other European countries. After the inaugural business had been disposed of, Herr Walter of Hamburg read a paper on Secondary Cathode Rays. Dr. Lewy-Dorn of Berlin described some methods of ascertaining the energy of the rays necessary for therapeutic purposes and showed an instrument devised by Herr Holzknecht of Vienna consisting of a milliampèremeter, a dosimeter, and a quantimeter. He said, however, that the energy of the rays could not be measured by instruments but must be ascertained empirically in every individual case. Some patients showed a marked reaction to very short exposures, whilst in others no reaction occurred even to very long exposures. Professor Grunmach of Berlin showed instruments for investigating the upper jaw through the mouth and exhibited radiograms of alveolar hyperostosis of the jaw. Dr. Grassner of Cologne showed a case of osteomalacia combined with rachitis. Dr. Schmidt of Berlin showed patients suffering from lupus and cancroids successfully treated by Roentgen rays. Dr. Stegmann said that he had obtained favourable results with the rays in cases of Graves's disease. Dr. Weik of Breslau said that the rays were useful in superficial cancer but had no effect on deep-seated malignant growths.

A Case of Ochronosis.

At a recent meeting of the Berlin Medical Society Dr. Pick showed specimens of a case of ochronosis. The patient, who was a woman, 77 years of age, had suffered from varicose ulcers of the leg to which she had for years applied bandages moistened with a solution of carbolic acid. The diagnosis of ochronosis was made during life because of the brownish-yellow colour of the skin and the cyanotic colour of the ears and hands. She eventually died with symptoms of hyperpyrexia and the necropsy revealed hæmorrhagic encephalitis and endocarditis, together with intense yellow pigmentation, especially of the internal organs. The brownish pigmentation was well marked in the cartilages of the ribs, the intervertebral discs, the trachea, the larynx, the joints, the aorta, and the kidneys. Microscopical examination proved that the pigment was diffused in the tissues which, however, were not altered; it had no characteristic spectroscopic appearance, was free from iron, was soluble in alkaline fluids, and was very like melanin. Dr. Pick was of opinion that the pigment did not come from the blood; it must be regarded as the symptom of an anomaly of metabolism produced perhaps by chronic poisoning with carbolic acid. Ochronosis is a somewhat rare pathological condition, as only eight cases have hitherto been described.

April 16th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Indian Budget and Sanitation.

NOTWITHSTANDING the prosperous state of the Indian finances as shown by the recent Budget and the speeches thereon the Government makes but a single reference to any expenditure on sanitary improvement. This sole item is a contribution to the Calcutta improvement scheme. Lakhs of rupees are to be spent on railways, irrigation, education, and remissions of taxation, in fact, in nearly every branch of Government administration, but with this exception there is not even a reference to sanitary schemes in any one of the numerous speeches made at the recent important meeting of the Imperial Council. It is impossible that all sanitary questions can be left to the local governments or to local bodies and both of these are continually hampered in their efforts for sanitary improvements by want of funds. The improvement of the health of the people and of the unhealthy conditions in which they live is as much an Imperial question as the prevention of famine or the construction of irrigation works and should be more seriously considered by the Central Government. If ever a Health Minister were wanted it is on the India Council. The Central Government is not, however, wholly to blame as the Civil Department actually saved £38,800 on medical and £88,000 on scientific and minor departments by the failure of local governments to expend in full their allotment.

Malarial and Other Fevers in Bombay.

The inadequate way in which sanitary evils are dealt with is exemplified in the recent appointment by the Bombay Government of a committee to investigate the prevalence of malarial and other fevers. The committee consists of the Surgeon-General, the Sanitary Commissioner, the Director of the Plague Laboratory, and one or two other medical men—all having other numerous and regular duties to perform. It is impossible that their report can be exhaustive. Statistics of Bombay city show that the deaths from fevers have varied within wide limits. In 1880 there were returned 7513 deaths; in 1896 there were 8776 deaths; and in 1904 only 2416 deaths. The statistics of Bombay have frequently shown many peculiarities and even in the two months of the current year the excess mortality is not explained by the amount of plague.

Plague Statistics.

The returns of plague throughout India show that though the annual recrudescence is later in appearing it is developing rapidly. For the week ending March 17th there were 13,325 cases with 10,782 deaths, as against 10,655 cases and 9058 deaths for the previous seven days. Bombay returned 1498 deaths; Madras, 42; Bengal, 4278 (a large increase); United Provinces, 3365; Burma, 402; Central Provinces, 879; Mysore, 89; and Kashmere, 77. The disease which may be said to have established itself in Rangoon about this time last year has spread to many districts. Mandalay has been attacked and up to March 24th no less than 1060 deaths have been reported. Plague is stated to be increasing rapidly in both Calcutta and Bombay but the figures are not published. At Bassein, in Burma, more than 3000 people have been inoculated and up to the present not one of them has been attacked although several deaths from plague are occurring every week. It is very unsatisfactory to note that an officer of the Indian Medical Service was prosecuted at the instance of the health officer in Bombay for neglecting and failing to give timely information to the municipal authorities regarding a case of plague and was fined Rs. 30.

Malaria in Bengal.

The Bengal Government has lately appointed a committee to inquire into the drainage of certain areas which are marked by the prevalence of fever. The duties of the committee will be to ascertain in what areas malaria is now prevalent, to investigate the causes of the disease and in particular to determine whether it is due to obstructed drainage, where malaria has been caused by obstructed drainage to decide whether a drainage scheme is practicable, and to prepare a list of practicable drainage schemes. It is to be noted that this committee is to be composed of two civilians and the Sanitary Commissioner. Further comment is unnecessary.

March 31st.

Obituary.

ARTHUR BLACKWOOD, M.D. R.U.I.

BY the death of Dr. Arthur Blackwood, of 100, Bedford-street, Liverpool, who died on April 6th, another martyr in the cause of medicine has gone to his rest. He graduated as Doctor of Medicine at the Royal University of Ireland in 1884 and soon afterwards became resident medical officer at the Liverpool workhouse hospital. Highly intelligent, upright, and honourable in character, he soon endeared himself to all at the hospital. He threw his best energies into the discharge of his duties and those seriously ill claimed his unremitting attention. Every indication gave promise of a useful and distinguished career until one day he was unwittingly inoculated in the finger in the discharge of his duties. His nervous system was rapidly affected and he became partially crippled and was subject to recurring attacks of ill-health for the rest of his life. He struggled manfully against his infirmities and as public vaccinator obtained the grant for excellent work year after year. An attack of pneumonia, acting upon an enfeebled frame, carried him off in a few days to the great regret of his numerous friends. He was about 44 years of age.

WILLIAM WOOD, M.B., C.M. EDIN., F.R.C.P. EDIN.

THE death of Dr. William Wood, of 5, Roxburgh-street and Donisla House, Edinburgh, occurred rather suddenly recently at Bridge of Allan, near Stirling, where he had gone for the benefit of his health. He was the eldest son of Mr. Frankland Wood, Sleights, Yorkshire, where he was born 41 years ago. After graduating in 1890 he started practice in Edinburgh and soon succeeded in building up for himself an extensive connexion. Some years ago he was appointed lecturer on materia medica and therapeutics and practical materia medica at the Edinburgh School of Medicine and was a very popular extramural teacher, attracting yearly a large class of students. He was also the author of "Elements of Practical Materia Medica and Pharmacy" and "Tables of Organic and Inorganic Materia Medica" and found time also for some original research. Though quiet and unassuming he was ever ready as a friend to offer counsel and advice, and his early death is a distinct loss to the profession and the community alike. He leaves a widow and three young children to mourn their loss.

JAMES MARTIN, L.R.C.P., L R.C.S. IREL.

THE death is announced of Mr. James Martin of Newry which took place on April 7th at his residence in High-street. For more than ten years he enjoyed a large practice in Newry and the County Down and was most popular with all classes. He was a director of the Dundalk and Newry Steam Packet Company and was highly esteemed in commercial circles. His death at the age of 42 years after only a few days' illness has caused much sorrow in the town.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. J. Mertznich, who is described as the *doyen* of Cologne medical men, at the age of 97 years.—Dr. T. Gelpke, director of the ophthalmic department of the Carlsruhe Deaconesses Hospital.—Dr. Aubenas, formerly professor of gynæcology in Strasburg, originally under the French and afterwards under the German *régime*.—Dr. Anton Lobmayer, director of the Agram Institute for Obstetrical Instruction, member of Parliament, and author of many popular works on hygienic subjects. He was 61 years of age.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examinations held recently the following candidates passed in the subjects indicated:—

PART I.

Biology.—M. C. Dence, Royal Free Hospital; W. H. Hooton, Leeds; and D. L. Schwabe, Royal Free Hospital.

Chemistry.—A. E. Hempleman, London Hospital; W. H. Hooton, Leeds; E. M. Johnstone, Royal Free Hospital; A. J V Mathews, St. Mary's Hospital; and D. L. Schwabe, Royal Free Hospital.

Materia Medica and Pharmacy.—C. J M. Lawrence, Manchester; and G. W. Simpson, London Hospital.

PART II.

Anatomy.—S. H. Andrews, St. Bartholomew's Hospital; E C. Banks, Manchester; H. R. Ibbotson and M. A. Kenny, Leeds; I. Pulteney, Royal Free Hospital; J. B. Tackaberry, Middlesex Hospital; A. D. Vernon-Taylor, Guy's Hospital; and G. F. Wilson, London Hospital.

Physiology.—S H. Andrews, St. Bartholomew's Hospital; S. S. Brook Guy's Hospital, D. M. Hunt, London Hospital; H. R. Ibbotson, Leeds; W. K. Kershaw, Manchester; H. E. Middlebrooke, London Hospital, I. Pulteney, Royal Free Hospital; J B Tackaberry, Middlesex Hospital; A. D. Vernon-Taylor, Guy's Hospital; and G. F. Wilson, London Hospital.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following students of the above school successfully passed the examination in Tropical Medicine held at the end of the twentieth session, January to April, 1906:—

*Captain S. Anderson, I.M.S.; *Dr. H. E. Arbuckle; *Captain B H. Dutcher, U S. Army; Dr A. G. Eldred (Colonial Service); Dr. H. Kramer, Dr. P H MacDonald (Colonial Service); Dr. B. Moiser (Colonial Service). *Dr G. J. Pirie (Colonial Service); Dr. A. Reid; Dr. W. Rogers (Colonial Service); Dr. W. E. Ruttledge, and Dr. A. L Wykham.

* With distinction.

UNIVERSITY OF ABERDEEN.—On April 5th the following received the degree of M.D.:—

*Lewis Davie Cruickshank, M B., Ch.B, Darlaston; *John Charles Galloway, M A., M B, Ch.B., Banff; Thomas Holt, M.B, C.M., Burnley; George Hall Johnston, M.B., C.M., Wath-upon Dearne (under Old Regulations); Dudley Macdonald Mackenzie, M B, Ch.B, London; Robert Mitchell, M.B, C.M., Doncaster (under Old Regulations); †Wilfred William Pearse, M.B, C M., Hong-Kong (under Old Regulations); Alexander Rose, M.B., C.M., London (under Old Regulations); and Arthur Leslie Sutherland, M.A., M.B, Ch.B, Darwen.

* "Honours" for thesis. † "Highest honours" for thesis.

The following graduated M.B., Ch.B.:—

First-class honours.—John Frederic Gill, B Sc., and William A. H. McKerrow.

Ordinary degrees.—Theodore Chalmers, G F. Dawson, M A., Mary W. Durno, A. D Fraser, A. S. Garden, J. F Grant, S. C. Howard, C. V. Impey, Adam Johnston, W. B. Keith, Arthur Kellas, A. S. Leslie, M A., J. S McConnachie, Joseph M Macdonald, J. G. McGregor, E. K. Mackenzie, N. P. Macphail, Sophie J. Meiklejohn, W. L. Millar, M.A., M. A. Milne, Stanley W. Munro, S. V. van

Niekerk, G. E. A. Petrie, James Raffan, Donald T. Skeen, F. J. Stuart, A. G. Troup, and W. H. Wishart, M.A., B.Sc.

TRINITY COLLEGE, DUBLIN.—At the Final Examination in Medicine held in Hilary term the following candidates were successful:—

Midwifery.—Ralph S. Oldham, John du P. Langrishe, Francis O'B. Ellison, William Hutcheson, Ernest D Caddell, Thomas D. Graham, Thomas King Edwards, Henry D. Drennan, Michael P. Leahy, Alfred C. Elliott, Ernest C. Phelan, Reginald Holmes, Dudley F. Torrens, John Gray, and Francis Casement.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Paul Strassmann, *privat-docent* of Gynæcology, has been granted the title of Professor. Dr. Hermann Triepel of Greifswald has been appointed chief of one of the departments of the Anatomical Institute with the title of Honorary Extraordinary Professor.—*Gratz:* Dr. Arnold Wittek has been recognised as *privat-docent* of Orthopædic Surgery, and Dr. Ernst Moro as *privat-docent* of Children's Diseases.—*Leipsic:* Dr. Alfred Bielschowsky and Dr. Arthur Birch-Hirschfeld, assistants in the Ophthalmic Institute, have been appointed to extraordinary professorships.—*Marburg:* Dr. Arthur Heffter of Berne has been offered the chair of Pharmacology.—*Naples:* Dr. Francesco Mastrosimone has been recognised as *privat-docent* of Surgical Anatomy and Dr. Giuseppe Verrotti as *privat-docent* of Dermatology.—*Vienna:* As Professor von Noorden does not commence the duties of the chair of Medicine until the winter session the lectures will be delivered in the meantime by Dr. Wechsberg, first assistant in the Medical Clinic.—*Warsaw:* Dr. J. Fedorow, professor of Gynæcology, is retiring.

THE INFANTS' HEALTH SOCIETY.—In the third annual report of this society the section dealing with the Infants' Hospital, Denning-road, Hampstead, N.W., states that although the infants admitted during 1905 were pitiable specimens, suffering from diseases of malnutrition, and averaged 50 per cent. below the normal standard of weight, yet the rate of mortality was lower than the mortality rate of infants under one year of age in any of the large towns of the United Kingdom. This clearly shows that with ordinary care the rate of infantile mortality can be very considerably decreased. The Infants' Hospital having been established three years it is felt by the committee of management that the experimental stage has been passed through and that the time has arrived when the hospital should be put upon a permanent basis. With this view the committee has under consideration a proposal to remove the hospital to a more central situation where accommodation may be provided for 40 infants and facilities given for the study of infant treatment which is not to any special extent provided in the leading London hospitals. The address of the secretary is 120, Victoria-street, London, S.W.

SCHOLARSHIPS FOR STUDENTS OF MIDWIFERY.—For the purpose of helping women in need of pecuniary assistance in obtaining a training as midwives the London Council Council is offering a number, not exceeding 12 a year, of scholarships of the value of £25 to suitable candidates from 24 to 40 years of age and ordinarily resident within the County of London. Candidates must satisfy the Council as to their need for assistance in obtaining this training and must enter into a bond with sureties to practise as midwives for two years within the Administrative County of London. They will be required to pass a qualifying examination equivalent to Standard VI. of the elementary school code, and preference may be given to those who produce evidence of a satisfactory training in nursing or who have had practical experience of sick nursing among the poor. The scholarships are to be applied in part payment of the fees for tuition, board, and lodging at one or another of the institutions recognised by the Central Midwives Board and approved by the County Council. The training necessary for the purpose of obtaining a certificate as a midwife at the present day is by no means an inexpensive one and this scheme of the London County Council will no doubt be of great assistance to many deserving women. Undoubtedly there will come a time when the supply of properly trained midwives will fall short of the requirements in most parts of the country and unless some help is forthcoming for those women who wish to take up this branch of nursing and who are unable to afford the expense entailed it will be difficult to meet the demand for trained midwives. This scheme of the London County Council should certainly prove successful and we hope that the county councils may see their way to promulgate similar schemes. It will certainly be money well spent.

THE University of Boston has invited Dr. Schott of Nauheim to lecture there next winter on Diseases of the Heart and their Treatment.

DEATH OF A CENTENARIAN.—The *Times* of April 17th states that Mrs. Isabel Stirling Waddell died on April 16th at Park Cottage, Cathcart, Glasgow, at the age of 104 years. She claimed to be the oldest woman in Scotland and was hale and hearty to the last.

THE UNIVERSITY OF BIRMINGHAM.—The following lectures are announced:—Professor J. T. J. Morrison will deliver a course of three lectures on the Legal and Social Relations of English Medicine, Past and Present, on Thursdays, April 26th, and May 3rd and 10th; a course of three lectures on Medical Ethics will be delivered on Thursdays, June 7th, 14th, and 21st, at 4 o'clock, by Professor R. Saundby; and the Ingleby Lectures for 1906 will be delivered on Thursdays, May 17th and 24th, at 4 o'clock, by Dr. C. E. Purslow, obstetric officer to the Queen's Hospital, Birmingham, who has taken for his subject the Management of a Case of Labour. The lectures will be delivered in the Medical Lecture Theatre and members of the medical profession and medical students are invited to attend.

DONATIONS AND BEQUESTS.—The executors of the late Mrs. M. A. Irwin have paid over to the Metropolitan Convalescent Institution the sum of £2316 19s., being one moiety of the ultimate residue of the testatrix's estate.—By the will of the late Mr. F. J. Horniman the following bequests are made: £1000 to the London Hospital, £1000 to the Sussex County Hospital at Brighton, £1000 to the Croydon General Hospital, £1000 to the Convalescent Home and Hospital at Lower Sydenham, £1000 to St. Mary's Hospital, Paddington, £500 to the Cornwall Convalescent Home for Men at Perranporth, under the management of the Royal Cornwall Infirmary, £1000 to the General Hospital at Truro, £1000 to the South Devon and East Cornwall Hospital, Plymouth, £500 to the Royal Cornwall Infirmary at Truro, and £1000 to the Surgical Aid Society.—The British Home and Hospital for Incurables, Streatham, has received a donation of £605 from "M. E. D."—As a result of the recent appeal to the Stock Exchange on behalf of the rebuilding fund of St. Bartholomew's Hospital the treasurer has received £2000. This is in addition to upwards of £1600 previously subscribed by members of the Stock Exchange for the same purpose.

SOCIETY OF ARTS.—The fourth and last Cantor lecture on Fire and Fire Risks was delivered at the Society of Arts by Professor Vivian B. Lewes on April 2nd. He said that in building construction oak beams were much safer than iron joists or girders in the event of fire breaking out. The high conductivity of metals was a serious drawback from this point of view, because, in the first place, a girder of some length would elongate by heat and tend to cause bulging of walls and, in the second place, thin iron partition doors in warehouses soon became red-hot and ignited material which was on the further side of them from the original fire. It must be more than 300 years since the first attempts were made to render wood non-inflammable, but it is only during the last 10 or 15 years that success has been attained—namely, by the use of a method which saturates the wood from the surface to the core with the fire-proofing material. Many chemicals have been suggested for this purpose, but the most useful of these antipyrenes, as they are now called, are ammonium phosphate and boric acid. In the fire-proofing process the timber is placed in large cylinders from which the air is extracted; the chemical solution is then run in and hydraulic pressure is used to force it into the timber. Rather more than four pounds of chemicals are thereby introduced into each cubic foot of wood. Wood treated in this way possesses all its original properties except that when held in a flame it only smoulders without taking fire. Small jets of flame sometimes make their appearance, due not to the burning of the wood but to the ignition of volatile hydrocarbons produced by the action of the heat. After a short reference to the fire risks connected with the industrial applications of electricity Professor Lewes spoke of the fire-proofing of dress materials by moistening them with boram (a substance which some of our readers may remember on account of a notice of it which appeared in THE LANCET of July 22nd, 1905, p. 264. When fire broke out in a theatre the danger to the audience was not so much from the fire itself as from the panic caused by the sight and smell of smoke. The method of ventilation followed in theatres caused a strong draught of air from the stage to the auditorium, which carried the smell of smoke at once over the whole house. Professor Lewes described a system by which this draught could be greatly reduced.

LITERARY INTELLIGENCE.—A new journal with international aspirations, the *Journal of Abnormal Psychology*, has been started in Boston, U.S.A. It will be published bi-monthly and the editorial management will be under the direction of Dr. Morton Prince, professor of nervous diseases, Tufts College Medical School, with whom are coöperating, among others, Dr. Hugo Münsterberg, professor of psychology, Harvard University; Dr. Charles L. Dana, professor of nervous diseases, Cornell University Medical School, New York; Dr. James J. Putnam, professor of nervous diseases, Harvard Medical School, Boston; Dr. August Hoch, Bloomingdale Asylum, New York; and Dr. Adolf Meyer, director of the Pathological Institute, New York State Hospitals. The journal is meant to serve the interests of both medical science and psychology and is primarily intended for the publication of articles embodying clinical and laboratory researches in abnormal mental phenomena. The field of investigation includes, for instance, such subjects as hysteria, hallucinations, delusions, amnesias, aboulias, aphasias, fixed ideas, obsessions, automatisms, alterations of personality, multiple personality, dissociation of consciousness, subconscious phenomena, relation of the mind to physiological processes, and neurasthenic and psychasthenic states. In discharge of its international functions the journal will contain articles printed in French or German if expressly requested by the author. Communications should be addressed to Dr. Morton Prince, 458, Beacon-street, Boston.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the above society was held on April 11th, Mr. Alfred Willett, Vice-President, being in the chair. 12 members were present. Since the last court three widows, annuitants of the charity, had died; one had received the sum of £697 in grants, another £372, and the third £651 10*s.*; their husbands had each paid in subscriptions only £52 10*s.*, being the amount representing 25 years' subscriptions, after paying which no further payments were required. The death of one of the directors was reported. An application for relief was received from the widow of a late member and a grant at the rate of £50 *per annum* was recommended. Ten letters had been received since the last court from widows of medical men asking for relief, but this had to be refused owing to the fact that their husbands had *not been members* of the society. Proposals for membership from three medical men were considered and the three were duly elected. The amounts received by the annuitants compared with the aggregate sum of subscriptions are striking evidence of the great advantages of this society which cannot be too *strongly* urged upon the members of the medical profession resident within 20 miles of Charing Cross. Full particulars will be sent on application to the secretary. The annual general meeting will be held on Thursday, May 3rd, at 5 30 P M., at the offices of the society, 11, Chandos-street, Cavendish-square, London, W.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 11TH.

Overcrowding in Cities.

MR. DUNDAS WHITE asked the Secretary for Scotland whether he was aware that according to the recent investigations of Mr. Arthur Sherwell, one-third of the population of Edinburgh and one-half of the populations of Glasgow and Dundee lived under conditions of overcrowding; and what steps, if any, it was proposed to take in the matter.—Mr SINCLAIR answered In spite of inquiry it has not been found possible as yet to obtain any published result of Mr. Sherwell's investigations. If supplied with the data on which the question is based it shall receive my consideration.

Infant Mortality.

MR. DUNDAS WHITE asked the Secretary for Scotland what were the death-rates among infants less than a year old throughout Scotland as a whole, and in Edinburgh, Glasgow, Aberdeen, and Dundee respectively, for the year 1905; whether these death rates were excessive; and what steps, if any, it was proposed to take in the matter.—Mr. SINCLAIR replied: The facts for the four burghs for the year 1905 are as follows—Edinburgh, 124·8; Glasgow, 130 8; Aberdeen, 138·5; and Dundee, 132·5. While these figures could hardly be called excessive as compared with those of other large towns in the United Kingdom there is no doubt that it is possible to reduce them. It is hoped that the steady improvement in sanitation will conduce to this. In addition, steps have been taken in Glasgow and Dundee to deal directly with the question by the appointment of health visitors, lay and medical, and by the establishment of municipal depôts for sterilised milk. Similar measures are under consideration in Edinburgh and Aberdeen.

Coloured Medical Men and the West African Medical Service.

MR. NOLAN asked the Under Secretary of State for the Colonies whether coloured medical men of African origin or descent were excluded from the West African Medical Service; and, if so, upon what grounds—Mr. CHURCHILL answered: Coloured medical men of African origin or descent are ineligible for the West African medical staff but are eligible for certain other public appointments in the Gold Coast, Sierra Leone, and Lagos. The West African medical staff is constituted principally for the purpose of safeguarding the health of the European officials of the colonial governments, and West African native medical officers would not, as a rule, command the confidence of these Europeans.

BOOKS, ETC., RECEIVED.

APPLETON, SIDNEY, 25, Bedford street, Covent Garden, *London*, W.C.

The Real Triumph of Japan the Conquest of the Silent Foe. By Louis Livingston Seaman, M.D., LL.D., late Surgeon-Major, U.S., V.E., Author of "From Tokio Through Manchuria with the Japanese," &c. *Price* 6*s.* net.

Price not stated. Vol. VII. (New Series), Part I., February, 1906. A *New* Pathogenic Louse; Anatomy of Gastrodiscus hominis; Revision of the Sarcopsyllidæ; the Maiotic Process in Mammalia. *Price not stated.*

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

JONES, H. TRAVERS, M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer at the Hospital for Epilepsy and Paralysis, Maida Vale, W.

LENNANE, GERALD QUIN, F.R.C.S. Eng., L.R.C.P., has been appointed Medical Officer of Health of the Borough of Battersea.

MACGILVRAY, W. J. HOOKER, L.R.C.P., L.R.C.S., L.M. Edin., L.F.P.S., L.M. Glasg., has been appointed Medical Officer to Fallowfield and Withington *District* of the Royal Rusholme Provident Dispensary, Manchester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARBADOS GENERAL HOSPITAL.—Junior Resident Surgeon. Salary £200 per annum, with quarters.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80 with fees.

BIRMINGHAM, UNIVERSITY OF.—Assistant Lecturer on Pathology and Bacteriology. Stipend £250 per annum.

BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £135 per annum, with board, apartments, washing, &c.

BRITISH LYING-IN HOSPITAL.—Physician.

BUXTON, DERBYSHIRE. DEVONSHIRE HOSPITAL.—*Assistant House* Surgeon. Salary £70 per annum, with apartments, board, and laundry.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £150 per annum, with apartments.

CENTRAL LONDON THROAT AND EAR HOSPITAL, *Gray's Inn-road*, W.C.—Third Registrar (honorary).

CHARING CROSS HOSPITAL.—Assistant Physician.

CRONSTADT, SEAMEN'S HOSPITAL.—*Resident* Medical Officer. Salary £180 per annum, with lodgings, lights, fuel, and attendance.

DOUGLAS, ISLE OF MAN, NOBLE'S ISLE OF MAN HOSPITAL AND DISPENSARY.—Resident House Surgeon, unmarried. Salary £90 a year, with board and washing.

DUDLEY, GUEST HOSPITAL.—*Assistant* House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.

EAST SUFFOLK AND IPSWICH HOSPITAL.—*Third* House Surgeon. Salary £50.

ESSEX AND COLCHESTER GENERAL HOSPITAL.—*House* Surgeon. Salary £100 per annum, with board, washing, and residence. Also Honorary Assistant Surgeon.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Surgeon.

FAZAKERLEY, CITY OF LIVERPOOL INFECTIOUS DISEASES HOSPITAL.—Assistant Resident Medical Officer, unmarried. Salary £120 per annum, with board, washing, and lodging.

HALSTEAD UNION.—Medical Officers for Fourth and Fifth Districts. Salary of former £36 per annum and fees and of latter £70 per annum and fees.

HELLINGLY, EAST SUSSEX COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £200 per annum, with board, apartments, and washing.

HEMEL HEMPSTEAD, WEST HERTS INFIRMARY.—House Surgeon and Assistant Secretary, unmarried. Salary £110, with rooms, board, fire, lights, washing, and attendance.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence.

HULL ROYAL INFIRMARY.—*Honorary* Assistant Ophthalmic Surgeon. Also House Physician, unmarried. Salary 80 guineas per annum, with board and apartments.

LANCASTER, ROYAL ALBERT ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £125 per annum, with board, apartments, and washing.

LEICESTER INFIRMARY.—Assistant Surgeon.

LISCARD, WALLASEY DISPENSARY AND VICTORIA CENTRAL HOSPITAL.—House Surgeon. Salary £100, with apartments, board, and service.

MACCLESFIELD GENERAL INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with board and residence.

MANCHESTER, HULME DISPENSARY, Dale-street.—Honorary Surgeon.

MONTROSE ROYAL ASYLUM, Sunnyside, Montrose.—Senior Assistant Medical Officer. Salary £200 per annum, with board, *lodging*, &c.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medical Officer. Salary £70 per annum, with board, residence, and washing.

OLDHAM INFIRMARY.—Junior House Surgeon. Salary £75 per annum, with board, residence, and laundry.

OXFORD, LITTLEMORE PAUPER LUNATIC ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £120, rising to £150, with rooms and board.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Second *Honorary* Anæsthetist.

SWANSEA GENERAL AND EYE HOSPITAL.—House Surgeon. Salary at rate of £50 per annum first six months, £75 per annum after, with board, apartments, washing, and attendance.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

VIRGINIA WATER, SURREY, HOLLOWAY SANATORIUM, St. Ann's Heath.—Junior Assistant Medical Officer. Salary £175 per annum, with board, lodging, washing, &c.

WARRINGTON INFIRMARY AND DISPENSARY.—Junior House Surgeon, unmarried. Salary £100 per annum, with residence and board.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £50 per annum, with board, residence, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Assistant Anæsthetist. Also Second Assistant Anæsthetist. Also Casualty Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

BURGESS.—On April 14th, at 195, High-street, Oxford-street, Manchester, the wife of Arthur H. Burgess, F.R.C.S., of a son.

COLTART.—On April 15th, at Granville House, Fulham, the wife of Guy H. Coltart, M.B. Lond., M.R.C.S., L.R.C.P., of a son.

MARSHALL.—At 25, Chester-street, Edinburgh, on April 12th, the wife of Major D. G. Marshall, I.M.S. (retired), of a son.

REIDY.—On April 13th, at 314, Commercial-road, E., the wife of J. Reidy, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of a son.

SHELDON.—On April 14th, at Cornwall road, Notting-hill, W., the wife of Walter Sirr Sheldon, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

STEPHENS.—On April 11th, at Seaforth House, Hoylake, Cheshire, the wife of J. W. W. Stephens, M.D. Cantab., of a son.

WARREN.—On Sunday, April 15th, at 15, Lansdowne-crescent, W., the wife of Alfred C. Warren, M.A., M.R.C.S., L.R.C.P., of a son.

WILSON.—On April 12th, at Ripon-road, Harrogate, the wife of H. Douglas Wilson, M.D., of a daughter.

MARRIAGES.

ELLIS—BARNES.—On the 16th April, 1906, at St. Mary's Church, Kippington, near Sevenoaks, Kent, by the Rev. H. Percy Thompson, M.A., assisted by the Rev. H. T. Knight, M.A., Leonard Erasmus Ellis, M.D. Brux., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Lond., of Clarendon Park, Leicester, to Evelyn le Hunte, only daughter of J. F. E. Barnes, Esq., C.M.G., M.I.C.E., of Pietermaritzburg, Natal.

SUTHERLAND—SUTHERLAND.—On April 11th, at Trinity Presbyterian Church, Clapham-road, S.W., John Sutherland to Annie Christina Sutherland, M.D.

DEATHS.

HALL.—On Good Friday morning, April 13th, 1906, at "Tresco," Ballards-lane, Finchley, N., Charlotte, wife of James Hall (formerly of West Bromwich) and mother of J. Field Hall, M.B., in her 73rd year.

TIMES.—On April 10th, at Exmouth, Devon, Lawrence Kingston Times, M.R.C.S., late of Manchester-street, London, W., aged 60.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

BOOKS BOUND IN HUMAN SKIN.

IN the museum of the Bristol Royal Infirmary is a book which possesses one particular feature that certainly is not attractive yet seldom fails to arouse interest when attention is drawn to it. The book on superficial examination presents no very striking appearance. In aspect, it is nothing more than a moderately old volume bound in embossed leather and discoloured by age. In the centre of the cover is a representation of a gallows with the words below, "*Cutis vera Johannis Horwood.*" Inside the covers are numerous legal and other documents that tell much about John Horwood. There are copies of statements as to what he did, descriptions of how he met with his death and of what happened to his body after death, even to details of the method by which his skin was tanned. Such an extract as the following gives some insight into the chain of events recorded. "Let him be hanged by the neck until he shall be dead, on Friday the thirteenth day of April instant, and let his body be delivered to Mr. Richard Smith of the city of Bristol, surgeon, to be anatomised." The last clause gives the name of the gentleman responsible for the curious book and shows also that the unfortunate man had been put into his hands by the law. John Horwood was a lad, aged 18 years, who, angry with a girl, had thrown a stone at her, which fractured and indented her skull. Death followed a surgical attempt to raise the depressed bone but although treatment then failed in these days of antiseptic surgery the girl would very probably have recovered. When this fact is borne in mind the following remarks of the surgeon, Mr. Richard Smith, have an especially melancholy interest. On the day of execution he was present in a room in which the prisoner said farewell to some of his friends. The description by the surgeon of what happened after the farewell runs as follows. "He now wrung his hands bitterly and seemed in great distress and said 'O Lord! O Lord!'" Having been bound by the attending constables he was led out, the chaplain reading the burial service. "Almost everyone was greatly affected, many shed tears. I certainly at the moment felt an indescribable sensation of depression and lowness of spirits." The surgeon who, no doubt, had been present at many death-beds and operated in the days before chloroform was used to abolish the pain of operations, and consequently was not only familiar with death but in discharging his daily duties often caused great suffering, watched the scene until the noose was adjusted round the prisoner's neck, and then he says, "My courage, if courage it is to be called, failed me. I perceived that the fatal moment was approaching and was unable to look any longer upon the criminal."

Such were the feelings of the man who afterwards had the unfortunate youth's skin tanned in order to make a book cover. How complex is human nature! Many other aspects of human nature are to be seen when looking through the numerous documents connected with the trial. There is, for example, no waste of words to express sentiment in the following note at the foot of one of the papers by an officer of the Crown. "Mem. Saw him executed accordingly. C.S." Such a brief, business-like record reminds us of the illustrations which the historian Green gives of the way in which Thomas Cromwell "ticked off men's lives" amongst daily "items," even when the life was that of no less a personage than Sir Thomas More. "Item, to know the King's pleasure concerning Master More." In another field we may compare Captain Broke's laconic entry in his diary:—"A.M. Wrt. Lawrence. P.M. Took Chesapeake." There are several other instances of books bound in human skin. One especially notable is in the Athenæum at Bury St. Edmunds and is an account of the trial of William Corder, murderer of Maria Martin. The case is well known as the Red Barn murder and the discovery of the murder was made through a dream. Corder's skin was tanned for the purpose by George Creed, surgeon to the Suffolk General Hospital. A humorous side to the tragedy is given by a tale told by Macready to J. M. Bellew. Corder was hanged on August 11th, 1823, and on the same night Macready took the part of Macbeth at Drury Lane. When Duncan asked, "Is execution done on Cawdor?" a voice from the gallery said, "Yes, sir, he was hung at Bury this morning."

REFEREES IN LIFE ASSURANCE.

To the Editors of THE LANCET.

SIRS,—As I am always interested in matters relating to life assurance I should like to call your attention to a paper lately received from the Gresham Life Assurance Society. I was referred to as a "*friend*" of a widow, about 50 years of age, the secretary adding a line, "*kindly note there is no fee payable for this report.*" I have often been referred to as a *friend* for a non medical report but have never seen such a list of questions put to a layman. In fact, nearly all the questions are medical—except, perhaps, the second, where I am asked if she is of undeniable character and if her statements may be relied upon. Her moral character might be very bad but that is scarcely wanted by most offices. But to ask a layman if a lady has suffered from gravel or stone or rupture, amongst other diseases is, to say the least of it, peculiar. Very often the vicar of a parish is referred to and in this case it would have been hard on our vicar who is unmarried. If you could give space enough to print questions 7 and 10 in full it will show your readers the sort of questions a layman is expected *to* answer whether about a man or a woman. I wrote to the medical officers of the Gresham. They courteously replied and said the *fact of a friend given for* reference being a doctor was a pure accident. This, of course, I was aware of. But they evidently expect these questions about gravel, dropsy, &c., to be generally answered by a layman.

I am, Sirs, yours faithfully,

Highgate, April 10th, 1906. GEORGE FLETCHER, M.D. Cantab.

⁂ *Questions* 7 *and* 10 *to* which our correspondent refers are as follows: "7. Do you know, or have you any reason to believe, that she has been afflicted with gout, asthma, habitual cough, spitting of blood, insanity, apoplexy, dropsy, rupture, fits, gravel, stone, or any other disorder that has a tendency in any way to shorten life? Has she ever received any severe injury? 10. How many brothers and sisters has she living? and what is the state *of* their health? How many brothers and sisters are dead? At what ages *and of* what complaints did they die?" We quite agree with our correspondent that to ask a friend to answer such questions is *extraordinary* and, perhaps, *it* is even more so to expect him to answer them. Medical matters are now discussed in society with great freedom and with a corresponding amount of ignorance but we hardly think that the average layman would be prepared to say whether any given friend was free from, or afflicted with, any or all *of the complaints mentioned* in *Question* 7. *If* life assurance offices are *going to* continue *to* ask *laymen such questions* they might bring a little joy into the matter by adopting Artemus Ward's delightful census paper, one question in which ran, "Have you had the measles and, if so, how many?"—ED. L.

LOCAL GOVERNMENT BOARD ECONOMY.

THE Local Government Board is demurring to the refunding of £3 3s. paid by Mr. B. Neal, medical superintendent of the Wandsworth workhouse infirmary, to Dr. S. Spicer in respect to an operation performed on an inmate. The guardians were notified at *their meeting on April* 12*th* that the Board had inquired why it was necessary to call in "an outside medical practitioner, having regard to the permanent medical staff at the infirmary." It appeared from statements made by guardians that the inmate, a young woman, had suffered from an affection of the nose and *throat and that an operation had been performed* by Dr. Spicer with complete *success*. Indeed, according to a *lady member* of the board of guardians, the surgical operation had produced a most satisfactory effect on the girl's character and temperament, for whereas formerly she was "naughty" and could not keep a place she had now *become a model domestic servant*. In the circumstances the board considered that the specialist's fee of £3 3*s*. was money admirably laid out and with one voice they agreed that Mr. Neal ought to have the amount refunded to him. Canon Curtis, the chairman, said it seemed to him that it was a question of differentiating between the *rich* and the *poor*. *People* in comfortable circumstances had obtained for them the very best advice possible. He did not see why the like should not be done for the poor. It could not be expected that the medical staff of the infirmary would have a specialist's knowledge and *skill*. The *guardians decided to send* particulars of the case to the Local Government Board.

IS BARLEY WATER A SUITABLE FOOD FOR INFANTS?

To the Editors of THE LANCET.

SIRS,—It is probable that infants may digest barley water in some circumstances at any rate. Some years ago I was called to see an infant, six months old, and inquiring *into* the *diet as the mother* had *no milk* I was assured that it had absolutely nothing but barley water since birth; it was pale and thin but not starving as I expected and soon recovered and grew when milk was added to the diet with a little sugar and salt.—I am, Sirs, yours faithfully,

April 14th, 1906. W. M. KNIPE, M.R.C.S. Eng., L.S.A.

To the Editors of THE LANCET.

SIRS,—Having read the letters of "Curia," "M.R.C.S., L.R.C.P." and "Ceres" on the subject of barley water, &c., *instead of plain* water as a diluent for milk *in infant feeding* and considering that barley water, &c., are added to milk very often with the supposed object of aiding the digestion of casein when the real cause of the trouble may be a too high percentage of proteid, I think, therefore, it would be *of* very great interest if your correspondents, "Curia," "M.R.C.S., L.R.C.P." and "*Ceres*," would tell us what percentage of proteid it is their practice to give to normal infants at the following ages: two weeks, one month, three months, and six months.

Also will "Ceres" explain more *fully his meaning* of this sentence, used by *him in his* letter of April 7th, 1906, p. 1013. "It will be found that by this process the casein is prevented from curdling and the caseinogen modified." Is he *referring* to the casein of Halliburton *or* the casein of Hammarsten? It appears as *if* "*Ceres*" assumed that there were *two different* proteids, casein and caseinogen, present in normal milk. But Hammarsten's casein is essentially the same as the caseinogen of Halliburton, except in name, while Halliburton reserves the word casein for the curd produced with rennet.

I am, Sirs, yours faithfully,

LACTO.

April 10th, 1906.

THE WIGAN GUARDIANS AND THE COST OF VACCINATION.

JUDGING from the number of *questions* asked in the House of *Commons* and also from the reports of discussions which take place periodically at the meetings of various boards of guardians, it would appear that many Members of Parliament and many members of boards of guardians are desirous *of* paying *inadequately* for the work performed by public vaccinators. The legislature having *provided for* vaccination with calf lymph, the Local Government Board abolished vaccination stations and provided instead that the public vaccinator should visit the child's house and perform the operation with special precautions and *should look* into the surroundings of the inhabitants of the house, reporting if necessary to the sanitary authority. Much clerical work was added and two or more statutory visits are required. Now we have complaints *from certain guardians of* the great cost of vaccination, but surely the public cannot expect all the additional work *and* care for the nominal fee that was formerly paid for the operation performed at appointed vaccination stations. This, however, is what the Wigan board *of guardians* appears to expect. *Ever since the new* legislation came into force some *member of the board of guardians* has found in the cost of vaccination a reason for airing his eloquence. At a recent meeting a proposition was moved by a new member, by way presumably of justifying his existence on the board, to the following effect: "*That the Wigan guardians are in favour of* early legislation being promoted by the Local Government Board placing vaccination officers entirely under the control of the guardians, and that public vaccination and vaccination officers be paid by salary in lieu of fees, and that the said resolution be sent to the President of the Local Government Board." Dr. M. Benson, who has been a useful member of the board for some time and who is a member of the health committee of the town council, pointed out that the extra work placed on the public *vaccinator* by the *Vaccination Act of* 1898 necessitated an increased fee and urged that the public health authority and not the guardians was the proper authority for carrying out vaccination. After *further discussion the mover of the original motion* altered it, so that it should read as follows: "That the Wigan guardians are in favour of early legislation being promoted by the Local Government Board to transfer vaccination to the public health authorities and that payment of public vaccinators and vaccination officers be by salary in lieu of fees, and that the said resolution be sent to the President *of the Local Government* Board." This was adopted, unanimously.

HOW TO MAKE "HUMANISED" MILK.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly give me details of how to make "humanised" milk from ordinary cow's milk? I am not sure of the proper proportions of the added whey to the milk.

I am, Sirs, yours faithfully,

April 17th, 1906. B. (MEDICUS).

COMMUNICATIONS not noticed in our present *issue will receive attention in our next*.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (3 P.M.).

TUESDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), *West London* (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), *London Throat* (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), *Children*, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.).

WEDNESDAY (25th).—St. Bartholomew's (1.30 P.M.), University *College* (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), *Charing Cross* (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), *St. Peter's* (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, *Golden-square* (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.).

THURSDAY (26th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), *Charing Cross* (3 P.M.), St. George's (1 P.M.), London (2 P.M.), *King's* College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), *London* Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), *Royal* Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.).

FRIDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.) Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), St. Mark's (2.30 P.M.).

SATURDAY (28th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (23rd).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M. Council. 8 P.M. Casual Communications:—Mr. W. H. Dolamore: *Two Cysts ? Dentigerous.*—Mr. J. G. Turner: *Effects of Abscesses arising from Temporary Teeth.*—Mr. B. J. M. Phillips: (1) *Hypertrophy of the Gums;* (2) *Dentigerous Cyst.*—Mr. N. G. Bennett *Teeth Devoid of Enamel.*—Mr. W. J. May: *Absorbed Roots.*—Mr. W. S Nowell: *Models showing Delayed Eruption of Temporary Teeth following Rickets*

TUESDAY (24th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.) —8.30 P.M. Paper:—Dr. W. S. Fenwick and Dr. J. P. Parkinson *The Use of an Antistreptococcus Serum in the Treatment of Gonorrhœal Infections and in Certain Cases of Purpura Hæmorrhagica.*

WEDNESDAY (25th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.) —8 P.M. Annual Meeting. Election of *Officers for the ensuing year.* 8.30 P.M. Adjourned Discussion on Syphilis (resumed by the President, Dr. F. J. Smith). The following, amongst others, are expected to take part:—Dr. T. Shennan, Demonstration of Spirochæta Pallida; Dr. G. F. Still, The Disease as met with in Children; Dr. J. H. Sequeira and Dr. M. Dockrell, Syphilitic Affections of the Skin, Dr. W. J. McC. Ettles, General Treatment.

THURSDAY (26th) —HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W) —8.30 P.M. Paper:—Dr. G. W. Hill: *Artificial Aids to Hearing.*—Mr. W. H. C. Greene: *Simple Tumours and their Relation to Malignant Disease.*

FRIDAY (27th).—BRITISH ELECTROTHERAPEUTIC SOCIETY (11, Chandos-street, Cavendish square, W.) —8 P M. Council. 8.30 P.M. Dr. D. Arthur will show the West London Hospital X Ray Table. Paper:—Dr. W. F. Somerville (Glasgow) *The Influence of High Frequency Currents on the Surface Temperature of the Human Body* (illustrated with lantern slides)

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.) —8 P.M. Clinical Evening for the Exhibition of Clinical Cases followed by Discussion. Patients in attendance from 8 P M. to 9 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (24th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—11.30 A.M. Dr. H. Wright: Bacteriology. 2.15 P.M. Medical and Surgical Clinics.

WEDNESDAY (25th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.) —10 A M. Dr. H. Wright: Clinical Examination of Blood and Urine. 2.15 P.M. Medical and Surgical Clinics. 3 P.M. Mr. Bidwell: Intestinal Surgery.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Demonstration —Mr. Stuart-Low: Ear.

THURSDAY (26th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—11.30 A.M. Dr. H. Wright. Bacteriology. 2.15 P.M. Medical and Surgical Clinics.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.).—5 P.M. Mr. P. C. Mitchell: The Digestive Tract in Birds and Mammals. (Lecture I.)

FRIDAY (27th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road. W).—11.30 A.M Dr. H. Wright: Bacteriology. 2 P M. Dr. H. Wright Clinical Examination of Blood and Urine. 2.15 P M. Medical and Surgical Clinics. 3 P.M. Mr. Bidwell Intestinal Surgery

ROYAL SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—5 P.M. Discussion on the Consumptive at Home (opened by Dr. G. A. Heron) Sir R. D. Powell, Dr J. E. Squire, and Dr. F. C. Shrubsall are expected to take part in the discussion.

SATURDAY (28th).—ROYAL SANITARY INSTITUTE.—3 P M. Visit to Mount Vernon Hospital for Consumption at Hampstead.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Liverpool Daily Post, Lancashire Post, Leicester Mercury, West Hants Observer, Glasgow Citizen, Yorkshire Observer, Leicester Advertiser, Portsmouth Independent, Newcastle Chronicle, Cardiff Mail, Bury Times, Manchester Guardian, Glasgow Herald, Leeds and Yorkshire Post, City Press, Surrey Advertiser, Manchester Chronicle, Bristol Press, &c.*

Communications, Letters, &c., have been received from—

A.—Dr. A. P. Allen, Croydon; A General Practitioner.

B.—Dr. C. B. Barkley, Baltimore; Dr. J. F. Boa, Kildonan; B.; Messrs. Burroughs Wellcome and Co., Lond.; Birkenhead Borough Hospital, Hon. Secretary of; Mr. F. E. Bennett, Margate; Mr. Haydn Brown, Caterham; Dr. Francis T. Bond, Gloucester; Dr. William Bruce, Dingwall; Mr. Albert Benthall, Lond.; Bolingbroke Hospital, Lond., Secretary of the Building Committee of; Mr. W. Berry, Wigan; Dr. D. Bower, Bedford; Birmingham University, Dean of; Dr. D. Burney, Lond.

C.—Dr. George Carpenter, Lond.; Dr. Walter P. Cockle, Lond.; Calcutta, Health Officer of; Messrs. Callard and Bowser, Lond.; Messrs. W. Carling and Co., Hitchin; Dr. J. B. Cleland, Perth, Western Australia; Cumberland Infirmary, Carlisle, Secretary of; Cornwall County Council Sanitary Committee, Truro, Chairman of; Courtenay's Worcester Sauce Syndicate, Worcester; Carlisle Dispensary, Secretary of.

D.—Mr. A. J. Davey, Lond.; *Daily News* Sweated Industries Exhibition, Lond., Committee of; Devonshire Hospital, Buxton, Secretary of.

E.—Dr. E. J. Elliot, Oxford; Dr. G. Eichholz, Lond.

F.—Dr. George Fletcher, Lond.; Forfarshire Medical Association, Dundee, Secretary of; Fine Art Society, Lond.

G.—Dr. J. G. Glover, Lond.; Messrs. Gould and Portmans, Lond.; "Green," Lond.; Glasgow Royal Infirmary, Secretary of; Dr. H. M. W. Gray, Aberdeen; Glasgow Pathological and Clinical Society.

H.—Dr. Hervé, Lamotte Beuvron; Halstead Union, Clerk of; Hulme Dispensary, Manchester, Secretary of; Dr. Woods Hutchinson, Arrowhead, California; Messrs. Haasenstein and Vogler, Cologne; Messrs. Heal and Son, Lond.; Mr. Charles F. Hart, Honolulu; Hull Royal Infirmary, Secretary of; Mr. H. T. Hicks, Lond.

I.—Messrs. Isaacs and Co., Lond.; Incorporated Society of Trained Masseuses, Lond., Secretary of.

K.—Mr. C. B. Keetley, Lond.; Messrs. R. A. Knight and Co., Lond.

L.—London Chemical and Drug Co., Manager of; Leicester Infirmary, Secretary of; Mr. J. Lawrence-Hamilton, Brighton; Dr. J. G. Ledingham, Elstree; Dr. T. D Luke, Edinburgh.

M.—Mr. J. Moxon, Newport; Miss Ivy McKenzie, Dresden; Messrs. Mallett and Co., Bradford; Mr. W. J. Hooker Macgilvray, Fallowfield; Macclesfield General Infirmary, Secretary of; Medical Graduates' College and Polyclinic, Lond., Secretary of; Dr. W. H. Maidlow, Ilminster; Maltine Manufacturing Co., Lond.; Mr. R. Mosse, Berlin; Mr. E. W. Marshall, Manchester; Messrs. Manlove, Alliott, and Co., Nottingham; *The Medical Review*, Lond, Manager of; Dr. G. S. McKay, Wetherby; Dr A. M. Mitchell, Guildford; Mr. Prosper Marsden, Liverpool; Mr. W. Marriott, Lond.

N.—Newport and Monmouthshire Hospital, Secretary of; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.; Noble's Isle of Man Hospital, Douglas, Secretary of.

O.—Messrs. Oppenheimer, Son, and Co., Lond.; Oxford County Council, Oxford, Clerk of.

P.—Mr. Y. J. Pentland, Edinburgh; Messrs. Parke, Davis, and Co., Lond.; Mrs. Pomeroy, Lond.; Press Manager, Olympia, Lond.; Lieutenant A. H. Proctor, I.M.S., Amritsar, India; Fleet-Surgeon A. M. Page, R.N., Malta; Messrs. Peacock and Hadley, Lond; *Phonographic Record*, Lond., Editor of.

Q.—Queensland, Department of Public Health, Brisbane, Secretary of; Queensland, Government Statistician of.

R.—Dr. J. D. Rolleston, Lond.; Messrs. Richardson and Co, Lond.; Rebman, Ltd., Lond; Dr. J. Rivière, Paris; Messrs. Reynolds and Branson, Leeds; Messrs. Robertson and Scott, Edinburgh; Dr. F. W. Forbes Ross, Lond.; Dr. J. W. Rob, Weybridge.

S.—Mr. Spencer, Aberystwyth; Dr. J. P. Steele, Birkdale; Mr. F. A. Upsher Smith, Chesterfield; Dr. C. Schulin, Billings, U.S.A.; Messrs. Squire and Sons, Lond.; Messrs. Smith, Elder, and Co., Lond.; Swansea General Hospital, Secretary of; Scholastic, Clerical, &c., Association, Lond.; Sanitary Wood Wool Co., Lond.; Messrs Street and Co., Lond.; Society for Relief of Widows and Orphans of Medical Men, Lond., Secretary of.

W.—Mr. C. Williams, Lond.; Messrs. F. Williams and Co., Lond.; Mr. A. J. Walton, Lond.; Mr. E. K. Williams, Pensnett; Mr. A. Weelands, South Shields; West Bromwich District Hospital, Secretary of; Messrs. W. Wood and Co., New York; Messrs. A. J. Wilson and Co., Lond.; Warrington Infirmary, Secretary of; Mr. Hamilton Whiteford, Plymouth; Mr. E. White Wallis, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. A. W. Aldridge, Northfield; Atomo Tobacco Co., Lond.; A. L; A. H. B.; Mr. A. Allen, Solva; Mr. S. E. Atkins, Hatherleigh; Aberdeen Town Council; A. C.; Messrs. T. and M. Armstrong, Lond.

The Oliver-Sharpey Lectures

ON

THE BEARING OF METABOLISM EXPERIMENTS UPON THE TREATMENT OF SOME DISEASES.

Delivered before the Royal College of Physicians of London on April 3rd and 5th, 1906,

BY EDMUND I. SPRIGGS, M.D. LOND.,
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE VICTORIA HOSPITAL FOR CHILDREN.

LECTURE I.

Delivered on April 3rd.

INTRODUCTION.

MR. PRESIDENT AND GENTLEMEN,—The true basis on which the knowledge of medicine rests is exact observation. Of all the processes of nature those which are concerned with the maintenance of life are the most illusive to the observer. Problems are presented which make great demands upon the resources of mechanical, physical, and chemical science. The inquiry into the source of the energy of the living body and into the forms in which its energy is manifested has occupied some of the greatest researchers of the last century, and not until recent times have chemical and physical methods been applied to the more difficult task of the measurement of these forces. More than commensurate with the difficulty, however, of the subject has been the brilliancy of the results obtained. The principle of the conservation of energy has been applied to living structures. The various forms of living activity have been not only correlated to their source, the potential energy of the food, but measured. Rübner, Laulanie, and a host of untiring workers have been able to show that in animals there is an absolute balance between the energy taken in as food and that used by the body and given out as heat and the chemical energy in the excreta. In order completely to estimate these metabolic processes as a whole it is necessary, not only to analyse the food and the liquid and the solid excreta, but also to ascertain the amount of oxygen taken in and carbon dioxide and water given out by the lungs. This has been done in man in a limited number of cases. On the other hand, a very large number of metabolism experiments has been carried out in which, although the respiratory analyses are wanting, the food and excreta have been daily examined over long periods, both in health and disease. In this way a mass of facts has accumulated concerning nutrition which cannot fail to be of paramount importance to medicine and the principles upon which diets are constructed have been put upon a sure foundation.

Our present object is to examine the results of metabolism experiments with reference to their bearing upon the treatment of disease. In many cases we shall find nothing that is new. The medical observation of the past and the experiment of the bedside have often suspected the truth and acted upon the suspicion with good results and thus a line of practice has come into use which the exact observation of scientific method has later confirmed. But those who have laboriously carried out accurate experiments have put medical knowledge upon firmer ground by transferring some statements from the list of what we think to the list of what we know. We speak of the science and art of medicine. Such researches confer a great benefit upon the science by relieving it of some of the oscillations of opinion and practice which only too frequently obscure the art. It is probable that I shall say nothing that is not known to my audience. My endeavour is rather to fulfil the design of the distinguished founder and to show some points in which practice is supported by "observation and experiment on man himself" and some perhaps in which it is not.

Since the object of these lectures is specifically to "encourage the application of physiological knowledge to the prevention and cure of disease and the prolongation of life" I shall devote the first lecture to the considerations of the principles upon which our knowledge of the nutrition of the body depends and their general application, and the second to the application of these principles in special investigations upon some pathological conditions. I shall be constantly referring to matter which is daily familiar to every medical man but from the point of view of the experimental evidence only.

PRELIMINARY CONSIDERATIONS.

The food supplies the necessary elements for the structure of the body and also energy for the various bodily activities. The elements are mainly supplied by proteids and salts. The energy is conveyed in different chemical substances, proteid, carbohydrate, and fat. The heat produced when these foods are oxidised in the body is the same as that given off when they are burnt outside the body, and can be ascertained for each foodstuff by combustion in a special calorimeter. The average figures from one gramme of the food substance used in the body have been found to be: for proteid, 4·1 calories; carbohydrates, 4·1; and fat, 9·3. In a metabolism experiment the proteid, carbohydrate, and fat in the fæces must be subtracted from those in the food, the difference being the quantity absorbed from the intestine. The carbohydrate and fat absorbed are wholly oxidised; not so, however, the proteid, for its nitrogen is excreted as urea and other substances which are not fully oxidised and therefore still possess some chemical energy. So that in estimating the total energy supplied by the food to the body we must also subtract this value from that of the absorbed food. The energy value of the urine is most accurately determined by direct estimation of the dry residua in a bomb calorimeter; it can be calculated approximately, however, if the amount of nitrogen in the urine and fæces be known. The oxygen taken in and the carbon dioxide given out by the lungs should also be measured, and since the respiratory quotient thus obtained varies according as to which foodstuff is being oxidised from it we may gain information on this point.

THE CONSERVATION OF ENERGY.

The proof of the law of the conservation of energy has been supplied in the case of man himself by Atwater and his fellow-workers. A chamber was constructed in which a man could remain for days at a time. The walls were fourfold and the spaces containing air were kept at the same temperature as the chamber by means of a thermo-electric apparatus. Thus no heat was lost to or from the chamber through the walls. Tubes led warm dry air to the chamber and the products of respiration were conducted away through a meter which measured the air and automatically took a sample for analysis at regular intervals. The heat produced by the individual was taken up by a kind of inverted radiator in the chamber, through which water flowed continually. The difference between the temperature of this water on leaving the chamber and that on entering it and the volume flowing through being known, the heat given off could be calculated. The evaporated water in the air leaving the chamber was also estimated and the heat lost from the body in converting this from the liquid to the gaseous state could then be also calculated. The food was measured and analysed and its caloric value determined and the urine and fæces were treated in the same way. These experiments were more complete than the previous ones on animals referred to in that the subject could do muscular work in the chamber. The muscular work of the body is of two kinds, internal and external. The internal is that done by the circulatory, respiratory, and visceral muscle. The energy thus set free is like that produced by the activity of the living cells of the body other than muscular, discharged as heat from the body. The external is that which results from external work such as raising a weight. In treatment we can control the external completely; the internal partially. In these experiments the subject worked a stationary bicycle and the bicycle was connected with a dynamo and the electrical current generated carried through a glow-lamp in the chamber and thus converted into heat and measured together with that given off from the body. The amount of work done and converted into heat was also separately measured by registering the electrical current produced. The potential energy of the substances actually oxidised in the body was thus compared with the kinetic energy produced, either as heat when the body was at rest or as heat and external muscular work, which was measured as heat. The experiments, which were 45, lasted several days, usually four, the total number of days observed being 143. The results were a complete confirmation in man of the above mentioned work in animals, both when the subject was at rest or doing work.

We know therefore, not by inference but by direct experiment, that in health the body produces no form of physical energy which is not derived from, and cannot be directly traced to, the chemical energy of the food or its own substance. Although the same complete prolonged experiment has not been done in disease, yet the results of a number of metabolism experiments, including calorimetric observations, furnish us with evidence, if such be wanted, that the same is true in disease. With this foundation to work upon, the carrying out of observations upon nutrition in man becomes a much more simple matter. Such detailed experiments as the above detailed one of Atwater required an extremely costly apparatus and the services of about 12 skilled workers. But since the relation of the food energy to that evolved from the living organism is now definitely known we can calculate from the food consumed the energy which the body uses without making a calorimetric experiment. An ordinary metabolic experiment with a nitrogen balance-sheet will tell us whether nitrogenous food be laid on as proteid tissue and not burnt at once. Also, if respiratory analyses be made in a respiratory chamber, such as is constructed in a number of laboratories, the determination of the respiratory quotient will enable us to conclude whether in the case of tissue other than proteid being used up it be carbohydrate or fat.

In order to form clear ideas as to the management of disordered states of nutrition we must consider for a moment the uses to which the different foodstuffs are put in the body.

PROTEIDS.

Proteid food contains those elements of which the essential tissues and organs of the body are made, since these consist of protoplasm. It is therefore an essential foodstuff. The manifold activities of living protoplasm are only equalled by the bewildering complexities of the molecular groups composing it, now being daily unravelled by many workers. These groups are separated from each other by digestion and such as are needed for the reconstruction of tissue are built up again into protoplasm, while any excess taken is converted into urea and excreted within a few hours. The work done by the digestive organs in dealing with proteid is, as we shall see, considerable. We have to ask ourselves the question, Can we, in diseased conditions of the digestive system, or in those diseases, such as fevers, where the stomach certainly, and the whole alimentary canal probably, share in a general depression of function, carry out with advantage part of this work beforehand. To answer this we must know first whether the hydrolytic products of digestion of proteid can replace proteid in the diet and supply the needs of the body for nitrogenous tissue; and secondly, whether if this be so, there are any disadvantages attached to their use. The reply to the first question is an affirmative. Albumoses, peptones, and even the groups of fractions obtained by prolonged pancreatic digestion, amido-bodies and their congeners, no longer proteid in nature, have been shown to be capable of keeping the animal body in nitrogenous equilibrium. The albumoses form the major part of some prepared foods, such as somatose. Metabolic experiments show, however, that these substances are far from being desirable, from a dietetic point of view, either in health or disease. True, they are normal products of digestion, but an examination of the intestinal contents shows that under normal conditions they are only present at any one time in minimal quantities. Each step in the disintegration is rapidly succeeded by the next, or by the removal of the product formed through absorption. But when albumoses are given in bulk in the food a considerable quantity is present at one time and irritative qualities are shown to be possessed which cause increased secretion, diarrhœa, and lessened absorption. For instance, Hildebrandt[1] in a man showed by analyses of the fæces that 87 per cent. of proteid given (which contained 23 grammes of nitrogen per day) was absorbed. On replacing about a quarter of this proteid with somatose the absorption sank to 73 per cent. On replacing two-thirds with somatose only 67 per cent. was absorbed. Still less favourable figures have been obtained by Neumann, Salkowski, Bornstein, and Ellinger. Small quantities added to the diets are better used, though by no means so well as ordinary proteid. These substances are, therefore, less acceptable to the alimentary canal than the original proteid. The same is true of sugar as compared with starch, the natural form in which carbohydrate is taken. We may seriously question whether peptonised milk has any advantages as a nutriment. The mixed products of digestion introduced into the stomach call forth gastric juice and ordinary milk calls forth less than any other food. Since the milk is digested normally there seems to be no need to substitute for it a partially digested fluid which will increase the gastric activity unnecessarily without any corresponding benefit to nutrition and with the possible disadvantages mentioned above. Peptonised milk does not clot in the stomach like ordinary milk but the formation of a hard clot can be prevented by dilution or by adding 20 cubic centimetres of 25 per cent. sodium citrate to each litre, or to some degree by thickening it. We must also remember that if albumoses or peptone be present in any considerable quantity their bitter taste becomes noticeable.

FATE OF PROTEID.

When any quantity of proteid has been digested there is an early excretion of urea—i.e., within 24 hours an amount of nitrogen corresponding to that ingested appears in the urine, except in such cases as are laying on flesh. Half of this urea excretion may occur within seven hours.[2] This fact suggests that the proteid taken in has not been built up into body tissue and thus the view has forced itself upon observers and has especially has been urged by Folin, that this rapidly excreted nitrogen is not needed by the body for structural purposes and hence the proteid containing it is hydrolysed and the nitrogen is excreted. The rapidity with which the elimination of nitrogen takes place is explained when we consider the probability that proteids are absorbed not as peptone but as amido-bodies and such simpler derivatives, the hydrolysis referred to above taking place chiefly in the intestine, and that such a proportion of these absorbed substances as is not needed to build up tissue is not reconverted into proteid at all but turned at once, as regards its nitrogenous moiety, into urea and excreted in the urine. The fate of the non-nitrogenous carbon-containing moiety is not definite, but it is no doubt oxidised to furnish energy in the same way as carbohydrate and fat. The hydrolysis of proteid involved in splitting off its nitrogen may take place with very little loss of energy, leaving all the carbonaceous part containing most of the energy of the original proteid available to be set free by oxidation. The suggestion naturally follows that this excess proteid may be replaced by carbohydrate of fat which, while serving equally well for the production of heat and energy by oxidation, would not throw upon the excretory organs the work of eliminating so much nitrogenous material. Experiment bears this out. Hirschfeld, Landergren, Swen, Kumawaga, and others have shown that nitrogen equilibrium can be maintained at a low level of proteid ingestion—e.g., even at 15 grammes of proteid per day for a time if abundance of carbohydrate and fat be taken. More convincing, however, are the observations of Chittenden on different classes of men, scientific workers, soldiers, and athletes, over long periods. These observations proved that about 50 grammes of proteid per day, or half the amount usually recommended, sufficed to keep these individuals in nitrogenous equilibrium and in health, without any increase, indeed with even a diminution in the total caloric value of the food taken. Other observers have fixed from 0·5 to 0·6 gramme of proteid per kilogramme per day as the lower limit advisable, which in a man of 70 kilogrammes is from 35 to 42 grammes. On the one hand, then, the theoretical reasoning from the fact that an excess of nitrogen is so rapidly eliminated from the body and on the other the practical result of experiment, substantially agree that proteid in greater amount is not necessary in health to supply the needs of the body, and increases the work of nitrogenous excretion with no apparent advantage.

Chittenden's results must remind everyone of acquaintances whose consumption of proteid is exceedingly small. They also suggest that many workers in the poorer classes are not so underfed as regards alcohol as they are supposed to be, but that rather are the richer classes overfed. Caspari and Glaessner investigated the metabolism of a married couple who lived upon a vegetable diet. The daily consumption of proteid was represented by from 5·3 to 7·8 grammes of nitrogen. On this was not only nitrogenous equilibrium maintained but some laid on. The absorption of protein was only from 74 to 75 per cent., but that of the other foodstuffs was above normal, for of the total energy of the food from 89 to 92 per cent. was utilised, these figures being as good as those for an ordinary diet. (Atwater: Available, i.e., absorbed, food was: energy, 90 to 92 per cent.; protein, 89 to 92 per cent.; fat, 95 to 96 per cent.; and carbohydrate, 97 to 98 per cent.)

---

[1] Zeitschrift für Physiologische Chemie, Band xviii., S. 180, 1893; see Ergebnisse der Physiologie, F. Voit, 1903, p. 693.

[2] Panum, see Speck, one hour in dog, healthy.

[illegible] and [illegible] have recently brought before the Physiological Society evidence that the physiologists working in a London laboratory utilised on the average 9·5 grammes of nitrogen a day. Such large quantities are obviously unnecessary for most individuals. Are they desirable from any point of view?* We must remember that we are dealing with average figures and people of large bulk will require more and it is important to remember this when fixing standards which are to apply to a number of people. Again, none of the physiologists above referred to, though living active lives, were doing continuous muscular work. It is true that Chittenden's subjects were some of them athletes and some soldiers, but they lost weight, and none were doing active continuous muscular work, such as thousands of workmen perform for from eight to 10 hours a day. Although, as we shall see in a few minutes, the energy for muscular work is not supplied from protein when other foods are available, yet the wear and tear of muscular tissues is supplied from protein and we should expect that a fairly liberal supply of it would be an advantage to hard workers. It is to be noted that in Atwater's experiments the subjects were excreting in the urine and therefore metabolising on an average from 15 to 18 grammes of nitrogen in the rest experiments† with a diet worth about 2700 calories and were practically in nitrogenous equilibrium. In the work experiments there was a daily loss of nitrogen in the urine in 19 experiments out of 21 with a similar amount of protein in the food and a caloric intake averaging 4340 calories. This does not prove that they could not have adjusted themselves to a lower standard, but they were evidently not perfectly adjusted to the higher one when doing hard work. It is stated that coolies work continuously through the day on a diet which contains from nine to ten grammes of nitrogen, of which from eight to nine grammes would be absorbed from the bowel. This being so, it is necessary to ascertain whether they do as much work as a European would in the same time and also how their body bulk compares with that of our workmen. Kumagawa used 2475 calories, of which 8·3 per cent. was protein and 83·7 carbohydrate—i.e., 50 grammes protein, of which 45 were used (hard work) = six grammes of nitrogen. With prolonged exercise the caloric value of the diet must be sufficient. We shall see that in some of Atwater's observations as much as 1000 calories of heat were recorded as given off from the body in two hours of working a bicycle hard against resistance. It is possible that more than the minimum requirement of protein is a benefit to a race, but this only long-continued careful observation can decide. The fiercest animals are carnivorous and take an excess of protein according to our standard, but this is perhaps because courage as well as cunning is necessary to enable them to obtain their food. There are certainly herbivorous animals, such as the *horse*, which in capacity, endurance, and strength are not inferior to the carnivora. This question is not one of vegetarianism, for it is possible to take an excess of nitrogen on a vegetable diet, and this is often done.

Whether the optimum amount of protein in a diet be as low as some of the above results may claim there is no doubt that a great many people eat a great deal too much of this form of food and the above results strengthen the hands of the medical man in his crusade against an excessive nitrogenous diet. We have before us definite proof that 50 grammes or two ounces of protein—i.e., 250 grammes or nine ounces of meat—is a sufficient proportion for an ordinary diet in health and in conditions such as chronic granular kidney, arterio-sclerosis, and gout may keep this figure before us as the total quantity to be allowed in the various foodstuffs. In diseases involving the kidneys and digestive organs we can therefore limit the protein to this amount with the full assurance that we are not in any way handicapping the nutrition of the body but, on the contrary, lessening the demands upon the digestive and excretory organs.

Reference may be made to Hopkins's suggestion that protein food is not only required to form protein tissue, but also to furnish certain molecular groupings necessary for the formation of some substances in the body, such as adrenalin and pigments, which exist in small quantities but are of great importance.

FAT AND CARBOHYDRATE.

Fat and carbohydrate are used to supply energy for all the bodily activities, whether manifested as heat or movement. Fat is weight for weight much the more valuable, but both are necessary; of the two carbohydrate is the more necessary (Kumagawa). The total caloric value of the diet must be made up to from 35 to 40 calories per kilogramme—i.e., about 2500 to 3000 calories for an adult who is doing moderate work. Chittenden's men used less but all lost weight, and this part of their work was not so well supported by evidence of other workers as is the reduction of protein.

REST IN BED.

We may now consider the food requirements of those who are not working. The effect of resting in bed was shown clearly by Atwater's experiments; he found that the energy given off by his subject during sleeping hours was nearly half that used when he was up and about in the chamber without doing any serious work; the figures show that the demand is 80 per cent. more in the latter case. This exact measurement is a striking example of the difference between keeping entirely in bed and being up, leaving external muscular work out of the question. In such diseases as anæmia, heart disease, respiratory disease affecting the circulation, fever, or any disease endangering nutrition, and in which the demands made upon the body are not balanced by its resources, it is clear that complete rest in bed is nearly 80 per cent. better than being kept in one room and not in bed. I say nearly 80 per cent. because the subject was not at this time taking food. Patients kept in bed, of course, require food and we shall see that digestion increases the oxidation processes in the body and we shall also see, however, that the work done in digestion varies considerably with the kind of food given and may be kept low. Internal work is done in the body by the circulatory and respiratory muscles, by the striated muscles in preserving their tone, and by the muscles involving the maintenance of the upright position. Zuntz calculated that the respiratory and circulatory work is about from 10 to 20 per cent. of the total calories of the fasting body. Johansson found that by controlling his involuntary muscular activity he could reduce his excretion of carbon dioxide by nearly a third. Speck has shown how quite imperceptible movements greatly increase the oxidation processes. Light increases the metabolism, doubtless through causing muscular movement. How great the total internal work is may be seen by the fact that in animals when the cervical cord is cut or curare is given the oxygen used and the carbon dioxide given off are reduced by one-half. In treatment we can considerably reduce these demands upon the individual by complete rest in the recumbent position. When digestive activity is absent, as in fasting with complete rest, the energy used by the body is at its lowest and we can trace the influence exerted by food.

EFFECT OF FOOD.

Atwater's figures show that in a resting experiment the carbon dioxide excretion was greater on the feeding days by 24 per cent. (33·8 : 27·3). The effect of an individual meal is also very noticeable when the oxygen as well as the carbon dioxide is measured. Both the intake of oxygen and the output of carbon dioxide show a rise of oxidation after taking food. There is much evidence that this is largely due to the muscular and secretory activity of the alimentary canal. The same increase of oxidation takes place in man, as shown by Lehmann and Zuntz in the fasting man Cetti. It also occurs after a saline purgative has been administered. It is, however, probably not merely due to the alimentary canal activity but also to an increase in the general metabolic activity of the body.‡ Nevertheless, such observations may yield useful information as to the degree of oxidation called forth by different foods which, with the above reservation, we may look upon as indicative of digestive work. It is often desirable in disease to feed the patient upon a food which will yield a maximum of energy to the body with a minimum of expenditure in its elaboration. The work of Speck in 1874§ and of Magnus-work in animals, both when the subject was at rest or doing work.

§ Ergebnisse der Physiologie.

We know therefore, not by inference but by direct experiment, that in health the body produces no form of physical energy which is not derived from, and cannot be directly traced to, the chemical energy of the food or its own substance. Although the same complete prolonged experiment has not been done in disease, yet the results of a number of metabolism experiments, including calorimetric observations, furnish us with evidence, if such be wanted, that the same is true in disease. With this foundation to work upon, the carrying out of observations upon nutrition in man becomes a much more simple matter. Such detailed experiments as the above detailed one of Atwater required an extremely costly apparatus and the services of about 12 skilled workers. But since the relation of the food energy to that evolved from the living organism is now definitely known we can calculate from the food consumed the energy which the body uses without making a calorimetric experiment. An ordinary metabolic experiment with a nitrogen balance-sheet will tell us whether nitrogenous food be laid on as proteid tissue and not burnt at once. Also, if respiratory analyses be made in a respiratory chamber, such as is constructed in a number of laboratories, the determination of the respiratory quotient will enable us to conclude whether in the case of tissue other than proteid being used up it be carbohydrate or fat.

In order to form clear ideas as to the management of disordered states of nutrition we must consider for a moment the uses to which the different foodstuffs are put in the body.

PROTEIDS.

Proteid food contains those elements of which the essential tissues and organs of the body are made, since these consist of protoplasm. It is therefore an essential foodstuff. The manifold activities of living protoplasm are only equalled by the bewildering complexities of the molecular groups composing it, now being daily unravelled by many workers. These groups are separated from each other by digestion and such as are needed for the reconstruction of tissue are built up again into protoplasm, while any excess taken is converted into urea and excreted within a few hours. The work done by the digestive organs in dealing with proteid is, as we shall see, considerable. We have to ask ourselves the question, Can we, in diseased conditions of the digestive system, or in those diseases, such as fevers, where the stomach certainly, and the whole alimentary canal probably, share in a general depression of function, carry out with advantage part of this work beforehand. To answer this we must know first whether the hydrolytic products of digestion of proteid can replace proteid in the diet and supply the needs of the body for nitrogenous tissue; and secondly, whether if this be so, there are any disadvantages attached to their use. The reply to the first question is an affirmative. Albumoses, peptones, and even the groups of fractions obtained by prolonged pancreatic digestion, amido-bodies and their congeners, no longer proteid in nature, have been shown to be capable of keeping the animal body in nitrogenous equilibrium. The albumoses form the major part of some prepared foods, such as somatose. Metabolic experiments show, however, that these substances are far from being desirable, from a dietetic point of view, either in health or disease. True, they are normal products of digestion, but an examination of the intestinal contents shows that under normal conditions they are only present at any one time in minimal quantities. Each step in the disintegration is rapidly succeeded by the next, or by the removal of the product formed through absorption. But when albumoses are given in bulk in the food a considerable quantity is present at one time and irritative qualities are shown to be possessed which cause increased secretion, diarrhœa, and lessened absorption. For instance, Hildebrandt[1] in a man showed by analyses of the fæces that 87 per cent. of proteid given (which contained 23 grammes of nitrogen per day) was absorbed. On replacing about a quarter of this proteid with somatose the absorption sank to 73 per cent. On replacing two-thirds with somatose only 67 per cent. was absorbed. Still less favourable figures have been obtained by Neumann, Salkowski, Bornstein, and Ellinger. Small quantities added to the diets are better used, though by no means so well as ordinary proteid. These substances are, therefore, less acceptable to the alimentary canal than the original proteid. The same is true of sugar as compared with starch, the natural form in which carbohydrate is taken. We may seriously question whether peptonised milk has any advantages as a nutriment. The mixed products of digestion introduced into the stomach call forth gastric juice and ordinary milk calls forth less than any other food. Since the milk is digested normally there seems to be no need to substitute for it a partially digested fluid which will increase the gastric activity unnecessarily without any corresponding benefit to nutrition and with the possible disadvantages mentioned above. Peptonised milk does not clot in the stomach like ordinary milk but the formation of a hard clot can be prevented by dilution or by adding 20 cubic centimetres of 25 per cent. sodium citrate to each litre, or to some degree by thickening it. We must also remember that if albumoses or peptone be present in any considerable quantity their bitter taste becomes noticeable.

FATE OF PROTEID.

When any quantity of proteid has been digested there is an early excretion of urea—i.e., within 24 hours an amount of nitrogen corresponding to that ingested appears in the urine, except in such cases as are laying on flesh. Half of this urea excretion may occur within seven hours.[2] This fact suggests that the proteid taken in has not been built up into body tissue and thus the view has forced itself upon observers and has especially has been urged by Folin, that this rapidly excreted nitrogen is not needed by the body for structural purposes and hence the proteid containing it is hydrolysed and the nitrogen is excreted. The rapidity with which the elimination of nitrogen takes place is explained when we consider the probability that proteids are absorbed not as peptone but as amido-bodies and such simpler derivatives, the hydrolysis referred to above taking place chiefly in the intestine, and that such a proportion of these absorbed substances as is not needed to build up tissue is not reconverted into proteid at all but turned at once, as regards its nitrogenous moiety, into urea and excreted in the urine. The fate of the non-nitrogenous carbon-containing moiety is not definite, but it is no doubt oxidised to furnish energy in the same way as carbohydrate and fat. The hydrolysis of proteid involved in splitting off its nitrogen may take place with very little loss of energy, leaving all the carbonaceous part containing most of the energy of the original proteid available to be set free by oxidation. The suggestion naturally follows that this excess proteid may be replaced by carbohydrate of fat which, while serving equally well for the production of heat and energy by oxidation, would not throw upon the excretory organs the work of eliminating so much nitrogenous material. Experiment bears this out. Hirschfeld, Landergren, Swen, Kumawaga, and others have shown that nitrogen equilibrium can be maintained at a low level of proteid ingestion—e.g., even at 15 grammes of proteid per day for a time if abundance of carbohydrate and fat be taken. More convincing, however, are the observations of Chittenden on different classes of men, scientific workers, soldiers, and athletes, over long periods. These observations proved that about 50 grammes of proteid per day, or half the amount usually recommended, sufficed to keep these individuals in nitrogenous equilibrium and in health, without any increase, indeed with even a diminution in the total caloric value of the food taken. Other observers have fixed from 0·5 to 0·6 gramme of proteid per kilogramme per day as the lower limit advisable, which in a man of 70 kilogrammes is from 35 to 42 grammes. On the one hand, then, the theoretical reasoning from the fact that an excess of nitrogen is so rapidly eliminated from the body and on the other the practical result of experiment, substantially agree that proteid in greater amount is not necessary in health to supply the needs of the body, and increases the work of nitrogenous excretion with no apparent advantage.

Chittenden's results must remind everyone of acquaintances whose consumption of proteid is exceedingly small. They also suggest that many workers in the poorer classes are not so underfed as regards alcohol as they are supposed to be, but that rather are the richer classes overfed. Caspari and Glaessner investigated the metabolism of a married couple who lived upon a vegetable diet. The daily consumption of proteid was represented by from 5·3 to 7·8 grammes of three weeks or more, fluid being supplied per mouth or per rectum. The secretion of gastric juice ceases and the ulcer is under the most favourable conditions for healing.

[2] Pannm, see Speck, one hour in dog, be

In treating such cases with injections of albumin water and sugar we must remember that the patient is very nearly completely fasting. For instance, a patient at present in St. George's Hospital took per day by the rectum 45 ounces of albumin water, each pint of which contains the white of two eggs (26 calories), one teaspoonful of sugar (14 calories), and a teaspoonful of salt. This is given in three doses of 15 ounces each. Each enema is therefore equivalent to about 30 calories and the total energy supplied per day is less than 100 calories, even supposing that the albumin is made use of.

The facts which have been observed upon fasting men and animals show that in such conditions careful attention must be paid to the following points. 1. The weight; the loss must be carefully observed and should not be more than from 1 to 1·5 per cent. of the total per day. As to the total loss, it is said that a man cannot survive a reduction of more than a third in acute hunger. Such a statement is of no clinical value, but any increase in the rate of loss is an indication to supply nourishment. 2. A fall of temperature below the normal limits is of sinister significance. This is a sign which is well known in cases of pathological starvation, such as that of œsophageal stricture. 3. A rise of the temperature above the normal contra-indicates fasting for more than a short time. Fever has been found in animals to lessen considerably the power of resistance to inanition. Nitrogen breakdown is never so little as in fasting without fever. 4. Sufficient fluid must be supplied. The body can only survive the deprivation of water for a short time. Experiments will be quoted later to show the effect of diminishing the water-supply on an ordinary diet. In the condition of which we are treating at present the fluid is usually given in an isotonic solution, such as normal saline, by the rectum. The quantity of urine should be watched and if it fall below the preceding average and become concentrated and the patient feels thirsty more fluid should be administered, if necessary by subcutaneous injection. Less water is necessary than when food is taken.

PARTIAL INANITION.

With partial feeding the period of resistance is much longer; indeed, in such a condition of subacute starvation the body may survive the loss of a much greater proportion of its weight than in complete hunger. The body has been known to become reduced by nearly half. We may class with this condition the treatment of enteric fever with whey. Taking König's analyses of milk, giving the percentage as follows: casein, 3·02; albumin, 0·53; fats, 3·69; and sugar, 4·88; and the heat values of the substances at 5·86 (casein), 5·74 (albumin), 9·23 (fat), and 3·95 (lactose), in one litre we should get a heat value of 740 calories. This is a high figure. The average for cow's milk obtained by direct estimation is about 670 calories (Langstein) per litre. Taking the higher we see that the constituents of the whey, the albumin and the lactose, give 30·42 and 102·76, equal to 223·18 calories in a litre or 1·76 pints, no allowance being made for the loss by imperfect absorption and in urea. So that two pints of whey a day at most mean a furnishing of 255·1 or about 250 calories per day, a nutritive value of a little more than half a pint of milk (212 calories).

NUTRIENT ENEMATA.

Turning now to the metabolism of patients receiving nutrient enemata, it is important to remember that we are dealing with a condition of partial starvation; enemata as usually given contain a fuel value of not more than 200 kilocalories in each enema. We must inquire how much food and of what kind is likely to be absorbed and what relation the quantity bears to the actual needs of the body. A fasting man (Cetti) used up tissue to the extent of about 30 calories per kilogramme.[9] During sleep and with as complete rest as possible the figure may be as low as 25 calories per kilogramme.[10] Even if only a portion of this be supplied it is of great value, as we have seen that a man can survive very much longer if a part of his energy be furnished than in hunger. In such conditions as gastric ulcer, when it may not be desirable to supply food by the mouth, this question is of great importance. We want to know what foodstuffs are made use of when introduced into the rectum and in what quantities. Voit and Bauer and Eichhorst showed that the absorption of albumin is aided by salt. A 1 per cent. saline solution is isotonic with the intestinal wall and forms a suitable medium for the conveyance of foods. Leube[11] carried out experiments in which meat and pancreas were mixed and concluded that a considerable quantity could be taken into the body in this way. Food was also given by the mouth, however. Boyd and Robertson[12] do not recommend this enema, however, as they find the putrefaction in the bowel was excessive. Ewald[13] obtained good results as to the absorption of eggs and other substances such as peptone. His observations were made for the most part on a neurotic woman who was also receiving food by the mouth. Brandenburg[14] concluded that only one-third of the casein of milk was absorbed, and other observers have also reported on this point unfavourably to casein. In 1903 Ehrström[15] investigated this point afresh. He points out that O. Cohnheim has shown that casein can be directly broken down by the erepsin of the intestinal juice without previous peptonisation, while other proteids cannot. On the other hand, it is probably more easily acted upon by bacteria. The following enema was administered two or three times a day to a patient with carcinoma of the cardiac orifice: 50 grammes of dextrose, 150 grammes of warm milk, and 15 grammes of proton (a combination of soda with caseinogen). This has a heat value of 350 calories. No abnormal fermentation was observed. An analysis of the fæces showed that 80 per cent. of the nitrogen was absorbed. He believes that the caseinogen was really broken down—that is, digested—in the bowel. If this substance be introduced into the blood directly it appears in the urine, but an investigation of this point by means of a frequent examination of the urine showed that this did not occur. Bial[16] mentions a research by Zehmisch,[17] which I have not read, in which enemata were given consisting of milk, eggs, sugar, and salt. The proteid and fat were very badly absorbed, the figures for absorption being: 1·5 per cent. proteid, 6 per cent. fat, 67 per cent. sugar, and 31 per cent. salt. These results are exceedingly unfavourable except as regards the sugar. Bial made one-day observations upon himself on two occasions with a 10 per cent. solution of Witte's peptone. He found that 50 per cent. was absorbed and if alcohol were added 66 per cent., and recommends the following enema: peptone, lactose, and absolute alcohol, of each 25 grammes; tincture of opium, ten drops; and water up to 250 cubic centimetres; to be given three times daily. The enema contains no fat.

Boyd and Robertson[18] have recently carried out some very useful observations. Six patients were observed for six days each and different enemata were given, six hourly, no food being taken by the mouth, and the urine and fæces were analysed daily. They found that proteid in the form of milk and eggs is very little absorbed from the bowel. From 30 to 70 grammes were given and from four to 14 were absorbed. In two cases when the white of one egg was given just as much was absorbed, nine and 16 grammes, as in four cases with the whites of two eggs in which four, seven, ten, and 11 grammes were absorbed; therefore no definite relation existed between the amount given and that absorbed. The highest caloric value obtained in the day from proteid was 56 calories.

With fat results much more favourable were obtained than by the above-mentioned workers. We have seen that Zehmisch reported an absorption of 6 per cent. only and Munk and Rosenstein in their observations on a patient with a lymphatic fistula reckoned that about the same proportion was taken up when lipanin was introduced into the rectum. Boyd and Robertson found that from 12 to 51 per cent. of fat was retained from milk, the yelk of egg, and in one case from cod liver oil. The absorption was absolutely greater when more fat was given. In four enemas for the one day of two eggs, 47 grammes of dextrose, ten cubic centimetres of cod liver oil, with saline solution, there were 103 grammes of fat, of which 46 were absorbed, having a heat value of 426 calories. In others 24·35 and, as I have already mentioned, 51 per cent. was absorbed. Such a utilisation of fat in these emulsified forms is of great importance and exerted, as might be expected, a distinct proteid-sparing

[18] Loc. cit.

Levy (1893) has shown that more demands are made upon the digestive activity with a proteid diet than with any other and also that this increase of internal muscular and secretory work lasts a longer time than with carbohydrate and fat. (May this represent the rapid breakdown of unneeded nitrogen and the conversion of the non-nitrogenous moiety into carbohydrate for future use?) A meal of proteid produces a rise in the respiratory exchange of from 30 to 50 per cent. above that of the fasting animal.[7] Speck and Magnus-Levy found that in man the oxidation after taking meat is 30 per cent. higher than after taking sugar and butter and the increase lasts about four hours. It is also increased with the amount of meat taken. This oxidation begins before there is time for any appreciable amount of absorption to have taken place; it is not caused by injecting food substances into the blood directly (although the excretion of carbon dioxide is increased under this condition) and, as above mentioned, it may be imitated by increasing the activity of the intestine by means of purgatives. Here, again, we have unequivocal evidence in favour of limiting the proteid in the food as far as may be without prejudice to nutrition in diseased states, and especially in alimentary diseases, since it requires more digestive work than other foodstuffs. We can therefore lessen the internal work of the body by (1) rest in bed and avoidance of all excitement and (2) limiting the digestive work caused by allowing too much proteid.

EXERCISE: EXTERNAL WORK.

Exercise involving the performance of external muscular work increases the metabolism of the body very greatly, but not that of the proteid tissues, unless it be excessive, when there is a slight addition of excretion of nitrogen in the urine for a day or two after. Atwater's figures showed that a man during the night gave out 150 calories in two hours, in the same time doing moderate work 500 calories, and when a muscular man was working hard 1000 calories were used in two hours. The actual external work done is about a fifth of the energy discharged or even less. This is rather better than the yield of a steam engine, which gives about 15 per cent. of its total discharge of energy as work and the rest as heat. It is often necessary to prescribe exercise of a moderate nature and it is obvious that a more liberal diet is required, just as in health when muscular work is done. In some diseases, as, for instance, in those of the kidneys, we must know what kind of food must be added. Experiment shows plainly that it is not necessary to add proteid, for when other material is available the body tissues are not used up to furnish muscular energy. During rest one of Atwater's subjects gave out 436 calories; of this 40 were derived from proteid and 296 from fat or carbohydrate, probably from fat. When the same individual did muscular work the discharge of energy rose to 772 calories in the same time. That from proteid, however, only increased from 40 to 60, while 712 were derived from fat. Again, one day 543 calories were discharged as external work; this necessitated an increase in the production of energy of over 2000 calories. Nevertheless, the heat given off from proteid oxidised, as shown by the nitrogen balance, was substantially the same as on a rest day, being 434 calories as against 429. Hence the whole of the 2000 calories was supplied by the oxidation of non-nitrogenous substances.

Of course, if carbohydrate or fat is not available for the production of the energy required in muscular work proteid is used, but the proof that there is any advantage in using proteid is wanting, while we know that extra work devolves upon the alimentary canal and the kidneys in dealing with the excess of nitrogen and it is probable that the proteid first makes the carbohydrate required from its carbonaceous residue. If, then, a man taking exercise does not require a corresponding increase in his nitrogenous food carbohydrate or fat should be freely given. Metabolism experiments here give definite proof that either of these foodstuffs is available. Carbohydrate may have a slight advantage over fat but there is no practical difference. Fat furnishes more energy per gramme given and when we desire to keep the bulk of the food as low as possible it is convenient to use it in abundance, for one gramme of fat is equivalent to more than two of carbohydrate. Again, when carbohydrate is not utilised in the body or only partially utilised, as in diabetes, we are forced to rely mainly upon fat and proteid as energy furnishers. We shall consider in detail the forms in which fat can be given when considering the treatment of diseases of the stomach. Carbohydrate food is almost invariably well digested by the stomach when given in simple form, such as arrowroot. Even in the case of dilated stomach when fermentative changes are especially liable to occur, if lavage be carried out, this food is well borne and has, like fat, the advantage over proteid in gastric ulcer of not stimulating the secretion of gastric juice.

FASTING.

A large number of diseased persons are suffering from partial inanition. There are also cases in which abstinence from food is adopted as a therapeutic means, notably in gastric ulcer. A consideration of the processes of nutrition during fasting will be of help in dealing with such conditions. In the first place we may, I think, start with the premiss that it is *a priori* desirable to feed the patient, except in specially selected cases of those diseases in which the taking of food seriously favours the progress of the morbid condition. Fasting has been advocated as a universal system of dietetics, especially in acute illnesses.[8] But we know that fasting animals are more liable to contract acute infections to which they are exposed and less liable to resist the infectious process when contracted and must conclude that the same applies to man. And this is certainly confirmed by experience. When an individual is obliged to go without food for a longer or shorter time, the point of greatest importance is the quantity of storage material contained in the body, and especially of fat. The body uses as little of its actual—i.e., proteid—tissue as possible. For instance, von Noorden calculated that a man on the second day of fasting oxidised proteid and fat to the value of 1897 calories. Of this, only 10 per cent. came from proteid and the remaining 90 per cent. from fat. Cetti, who was not a fat man, used on the second day of a fast 1695 calories, of which 18 per cent. came from proteid and 82 per cent. from fat. Further, as the fasting days proceed the body uses less energy and the proteid excretion, which is usually about from nine to ten grammes per day, may sink as low as from three to four grammes of nitrogen per day after three weeks. The amount of energy used per kilogramme does not fall much, but as the body loses in weight the total energy used falls regularly. After a certain time the proteid tissues are called upon to supply all the energy needed, for the fat becomes used up or else the body loses the power of oxidising it, for some fat usually remains in the body even after death from starvation. In this case the nitrogen in the urine represents (1) the unavoidable tissue breakdown, probably equivalent to from three to four grammes of nitrogen; (2) the proteid used in producing energy which is increased after the fat is gone; and (3) the proteid broken down to form carbohydrate.

Towards the end of a hunger period, acetone, diacetic acid, and oxybutyric acid appear in quantity in the urine. It is noteworthy that acetone has been regarded as arising from fat, but that it appears in greatest quantity when that substance is present in least amount and when most of the energy is being furnished from the proteid. This, together with the fact that it may arise when abundance of fat is available, suggests rather that a deficiency of carbohydrate is the accompaniment of the formation of this substance. The suggestion of Embden and von Noorden that acetone may arise as a disintegration product of leucin, the remainder of the molecule containing the lactic acid group being synthesised to form carbohydrate, would also accord with this view. We should then suppose that proteid forms the carbohydrate and that acetone is a by-product and the appearance of this substance with diacetic acid in the urine would indicate that carbohydrate is required—e.g., fever and wasting diseases. Then in this one respect nutrition will be placed upon a more normal basis.

Since most of the observations on the metabolism of fasting people have been made when the patients were up we should expect that a fasting period would be much better endured with a subject in bed, for the demands made upon the body are in this case much less as shown above, first because the internal work of the muscular, circulatory, and respiratory system is at a minimum owing to the absence of exertion; secondly, the internal work accompanying digestion is absent; and thirdly, because the oxidation in the muscles necessary to maintain the body temperature is less owing to the body being warmly clothed. This is found to be the case, for fairly nourished women suffering from gastric ulcer have been found to bear easily a fasting period

BY D'ARCY POWER, M.A., M.B. OXON., F.R.C.S. ENG.,
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

MANY advances have been made of late years in connexion with the surgery of the blood vessels and to these advances the English-speaking races have contributed their fair share, though fortunately surgery, like science, knows no nationality and every improvement whether in theory or practice becomes at once the property of all mankind.

Surgical knowledge is based upon pathology and pathology itself is but a part of physiology. Improvements in physiology, therefore, acting through pathology, lead to improvements in the science and art of surgery. Physiologists have devoted much attention to the vascular mechanism and they have been so ably assisted by histologists that we have now a tolerably clear idea of the circulation of the blood and of the means by which it is maintained and regulated.

SURGICAL SHOCK AND COLLAPSE.

This knowledge at first sight would appear to be more useful to the physician than to the surgeon but the surgeon has employed it to advantage in elucidating the cause and the rational treatment of collapse and shock, conditions which every surgeon has long viewed with the utmost alarm because they so often put an abrupt end to his best planned operations. You all know the sequence of events as they occur in the surgery when a man is brought in from a railway smash, in the operating theatre during the administration of an anæsthetic, and in the wards when a patient is dying with a gangrenous appendix. Such conditions are bad enough in hospital practice; they are worse when they occur in private; worst of all when they have to be faced at home Need I draw you again the classical picture of a patient in a state of shock?—a picture drawn so well by my old master, Sir William Savory, that I cannot improve upon it:—

> The patient lies in a state of utter prostration. There is a striking pallor of the whole surface, most marked in the face. Even the lips are quite pale and bloodless There is a cold and clammy moisture upon the skin and often distinct drops of sweat upon the brow and forehead The countenance has a dull aspect and appears shrunken and contracted. There is a remarkable languor in the whole expression and especially in the eye which has lost its natural lustre and is partially concealed by the drooping of the upper lid, whilst the pupil is dilated and reacts sluggishly The nostrils too, are usually dilated. The temperature is reduced so that the patient shivers from time to time and complains of cold Muscular debility is extreme—apparent at a glance in the condition of the lips and hands—occasionally even in the relaxation of the sphincters The pulse is generally frequent, sometimes irregular, always very feeble, perhaps quite imperceptible. In this latter case, although the ear may detect the fluttering action of the heart, the pulse does not reach the wrist. The respiratory movements are short and feeble or panting and gasping, "wanting the relief of sighs," sometimes imperceptible, although in the majority of cases some action of the diaphragm may be detected by careful observation Vertigo with dimness of vision supervenes As a rule there is not complete insensibility, but the patient is drowsy and bewildered, yet conscious and often rational when roused. Blissfully unconscious of his perilous condition he dreams away his end, or roused by the fruitless activity of his attendants he may ask, "Is this death?" Sometimes the intellect is singularly clear and the senses are perfect, the hearing occasionally even peculiarly acute, whilst in the less extreme cases there are often nausea and vomiting with hiccough.

Starting with such a picture in his mind Crile[1] has carried out an important and elaborate research upon the blood pressure in surgery and has thrown his results into the form of an essay which gained him the Cartwright prize for 1903 The research, he says, was undertaken to study the cause of shock and collapse as it occurs in surgical practice and to obtain, if possible, some rational treatment for a condition which is of no rare occurrence in the practice of every operating surgeon.

The essential phenomenon in shock is a fall of blood pressure caused by exhaustion rather than by structural lesions and the fall is due to the blood accumulating in the veins and especially in the larger venous trunks. In shock, therefore, there is a condition of intravenous hæmorrhage. When the fall of pressure occurs gradually the patient passes into a condition of shock; if it occurs suddenly he is said to be in a state of collapse and a similar condition is produced by actual loss of blood as well as by other causes.

The tradition of different schools varies very greatly in the treatment of the shock and collapse following operations One surgeon administers alcohol as a routine method after every severe operation, another gives it before as well as after the operation, whilst a third never gives it at all. One orders digitalis, another strychnine, others strychnine and its antagonist nitroglycerine at the same time; whilst others, again, give hypodermic injections of ether even when the patient has been anæsthetised by ether. Atropin is injected hypodermically because the cutaneous circulation is thereby increased and in shock the patient has a cold skin. Others give caffein because it stimulates the heart. Ergotin is a favourite remedy in France, strychnine in Germany. We in England follow the German rather than the French plan and employ strychnine largely. But if the truth must be spoken and we examine the results obtained by those who stimulate their patients habitually and compare them with those obtained by surgeons who only resort to stimulation occasionally, it seems as though the better results were gained by the surgeons who reserve their remedies for really urgent cases. The treatment of surgical shock and collapse therefore is clearly empirical at the present time and Crile has done a useful work in undertaking an investigation upon the blood pressure in surgery with a view to ascertain by experiment the conditions under which it varies, for until these conditions are known there can be no rational treatment.

The questions to be answered in connexion with shock and collapse are the following: To what is the fall of blood pressure due? Is it caused by (*a*) exhaustion of the blood-vessels, *i.e.*, the anatomical periphery; (*b*) exhaustion of the heart; (*c*) of the centres, vaso-motor, cardiac, or respiratory, and if it is due to failure of these centres is it the result of an exhaustion or failure of action on their part or is it caused by the blood plasma passing through the walls of the blood-vessels? (*d*) if it is due to an exhaustion of one or more of these centres or organs would stimulation relieve the exhaustion or would further exhaustion follow the stimulation? In other words, is it better to lash the tired horse or to rest it? If only some of the centres or organs are exhausted would it be advantageous to stimulate those which are not affected while the exhausted ones are allowed to rest? Would it be advantageous to restore the blood pressure in such cases by harmless mechanical means if it were found possible to do so? Are not the centres governing the circulation automatic in their action and are they not all stimulated automatically? Moreover, are they not all stimulated to the point of exhaustion before the final circulatory breakdown known to us as collapse or shock? Is it better to depend upon drug stimulation of these exhausted centres or should reliance be placed upon their automatic stimulation?

Crile submitted these problems to the test of experiment and as far as possible subjected his experimental results to a clinical comparison in his surgical wards. He arrived by these means at results useful to every surgeon, for they deal with the various remedies that we are accustomed to employ in the treatment of the more severe cases of shock and collapse. He has summed up the results of his observations in the following words. In many cases the control of the blood pressure is the control of life itself. Surgical shock is an exhaustion of the vaso motor centre; neither the heart muscle, nor the cardiac centres, nor the respiratory centre are other than secondarily involved. Collapse is due to a suspension of the function of the cardiac or of the vaso-motor mechanism or to hæmorrhage. In shock therapeutic doses of strychnine are inert; physiological doses are dangerous or fatal. When it does not cause death increased exhaustion follows the administration of strychnine. It is impossible to make any distinction between external stimulation of the vaso-motor centre—such as is produced by injuries and operation—and internal stimulation by such stimulants as strychnine. Each in sufficient amount produces shock and each with equal logic might be used to treat the shock produced by the other. Stimulants of the vaso-motor centres are not contra indicated in shock and collapse. But in shock cardiac stimulants have only a limited range of usefulness, whilst their action may prove to be injurious. Stimulants may be useful in collapse because the centres are not exhausted. Saline infusions are not very useful in shock but they may be very effective in the treatment of collapse. The blood only tolerates a limited dilution with saline solution and action, much less nitrogen being passed in the urine. Hausmann has recently found that of a 15 per cent. solution of grape sugar 60·3 per cent. is absorbed in two hours, of cane sugar 51·5 per cent. at most, and of milk sugar 37·5 per cent. 10 per cent. alcohol delays absorption but its caloric value more than makes up. The sugar absorption is helped by 1 per cent. saline solution.

[1] *Blood Pressure in Surgery* an Experimental and Clinical Research By George W. Crile, A.M., M.D., Professor of Clinical Surgery, Western Reserve Medical College, Cleveland. 8vo

We see therefore that sugar is well taken up from the rectum. To exclude the possibility of its being simply broken down by bacterial action these observers applied to it an experiment used by Ehrström in the case of caseinogen. Dextrose was digested with fæces in an incubator and it was found that less than 1 per cent. is broken down in four hours. From the enemata 37 to 81 grammes of dextrose were taken up in the day, being from 150 to 330 calories in fuel value. No glycosuria was observed.

It follows from the consideration of the above figures that the feeding was effective. They recommend an enema of the yelks of two eggs, 30 grammes of dextrose (pure), and pancreatised milk to 300 cubic centimetres (ten ounces). In the experiments the caloric value actually taken up varied from 240 to 645 calories in a day. The average was 389. The enema here recommended contains 300 calories. Therefore four in the day contain 1200, and probably about 500 will be absorbed. The authors lay stress on the smallness of this value; and point out that Umber has shown that gastric juice is secreted into the stomach during rectal feeding, and that this would be prejudicial to an ulcer.

I think nevertheless that these results are encouraging to this method of feeding. 500 calories is nearly half the need of a woman of 50 kilogrammes lying in bed. At 25 calories per kilogramme she would require 1250 calories, and it is obviously very much better to supply 500 calories if the patient is in any danger of malnutrition than that she should break down more tissue still to furnish it herself. For instance, if she excreted ten grammes of nitrogen in the urine this means that 62·5 grammes of proteid are broken down, or 330 of actual flesh, and this would furnish 250 calories of the 1250 and the remaining 1000 calories would need the oxidation of 107 grammes of fat—that is, about 150 grammes of fatty tissue. But the 500 calories absorbed from the rectum would save a good proportion of the fat breakdown and although very little proteid is absorbed the other foodstuffs will still spare the tissue proteid, as, indeed, the figures in the above research show. Thus, although we must be perfectly clear that rectal feeding cannot supply the caloric need of the body, even under the most favourable conditions, it is shown to be a means by which we can introduce a valuable amount of food. The prospect of supplying any useful quantity of proteid is regarded by Boyd and Robertson as slight and indeed the quantity taken up was very small. But Ehrström's results with milk and proton and Bial's with peptone are suggestive that more success might be attained with those substances. Since 10 or even 20 per cent. of dextrose is taken up it is clear that it is not necessary under suitable conditions to have a fluid isotonic with the rectum, but the more nearly this is attained the more likely are the enemata to be borne for long periods. Dextrose, unless pure, contains irritating substances. The rectum must always be washed out daily and it is very important that sufficient fluid be given. Experience is showing that enemata of ten or 15 ounces can be retained if slowly given and they have the great advantage of needing less frequent administration. Cannon[19] showed that in the cat an anti-peristalsis of the large intestine is a normal occurrence and is also set up when a nutrient enema is passed into the rectum carrying the material to the cæcum, and may force fluid through the ileo cæcal valve, but only when sufficient bulk was present. There is much more chance of the contents of an enema reaching the upper part of the large intestine and even the small if a good quantity be given.

FEEDING AFTER INANITION.

Under normal conditions if the food taken into the body be in excess of that required there is a storage of energy in the form of fat. Although carnivora easily lay on proteid tissue this is not the case with man. In special circumstances, such as the provision of an excessive diet, enormously rich in proteid, given for short periods only, nitrogenous tissue may be laid on.[20] But, generally speaking, this is not so, except when the muscular tissue is growing in bulk under the influence of constant exercise. After a period of fasting, however, the condition is different and proteid is laid on rather than fat, just as during the fast fat is broken down rather than proteid—that is to say, when the body is from any cause below its weight or increasing in weight proteid is laid on. Von Noorden points out that in such circumstances the body will retain proteid from a diet which in the well nourished would lead to a loss of nitrogen. The retention of nitrogen is not a function of the amount of food but of the body cell. We may recall that the same is true of the use of oxygen by the body. The supply of oxygen in the lungs is in almost all cases sufficient, and increasing it does not increase the oxidation processes, since these depend solely upon the needs of the tissues. A girl who had fasted owing to an œsophageal stricture retained a quarter of the nitrogen given.[21] Beibtreu's hysterical woman[22] laid on over four grammes of nitrogen per day for 14 days on a diet containing 30 grammes. The observations of Popov[23] also showed how well nitrogenous tissue can be laid on and nutrition improved. Dr. W. Hale White and myself investigated the metabolism of a woman whose weight had fallen to 39 kilogrammes. She was confined to one room for eight weeks, massaged, and fed on an exceedingly liberal and varied diet. She illustrated well the amount of food which can be taken in such circumstances. Its energy value per day was over 5000 and more than 110 calories per kilogramme. After the first week from 35 to 46 grammes of nitrogen were taken daily and between 200 and 300 grammes of fat. The quantities of fat and proteid were thus approximately equal, the average proteid intake being 244 grammes and the fat intake 253 grammes. Abundant carbohydrate was also supplied in the form of bread, potatoes, other vegetables, puddings, milk, &c. The absorption was astonishingly complete, 96 per cent. of both nitrogen and fat being utilised. There was no diarrhœa, vomiting, or disturbance of digestion. A large amount of the nitrogen was retained and the case showed with what avidity the tissues retain this kind of food in inanition, as has been demonstrated by other workers. The weight increased from 39 to 52 kilogrammes—that is, she added a third of her original weight—in the eight weeks.

After fevers the same is true. Abramovitch in 1888, for instance, in a case of pneumonia after the fever had come to an end observed for four days, found that a man, aged 22 years, weighing 54 kilogrammes, retained 7·2 grammes of nitrogen per day. This is equivalent to 238 grammes, or about half a pound of proteid tissue a day. The diet contained 550 grammes of bread, 150 grammes of meat, and about a litre of soup. This was not excessive in heat value; the bread and meat would come to about 1650 calories. We cannot make a calculation for the soup and bouillon, but these would not add very much fuel value. Other observers since have confirmed these results in convalescence after acute illness.

The factors favouring the putting on of weight, including proteid and fat, after inanition from any cause are: (1) feeding at frequent regular intervals; (2) a varied diet; and (3) the removal of all causes of loss of energy—that is to say, all sources of unrest. From observations upon animals it is probable that flesh would be still better deposited if short fasting periods were intervened from time to time.[24] Even on an excessive diet, no fear need be entertained of producing any harmful degree of purin bodies in the organism if food be chosen with this object in view.[25]

LEEDS PUBLIC DISPENSARY: THE POST-GRADUATE COURSE.—A post-graduate course will be opened at this dispensary on April 30th next with an address by Mr. Jonathan Hutchinson, F.R.S. The clinical demonstrations will commence on May 8th. Further particulars will be supplied by the honorary secretary.

DAWLISH COTTAGE HOSPITAL.—Dawlish Cottage Hospital, which has recently been enlarged and rendered more efficient, at a cost of £1200, through the generosity of Mrs. Nosworthy, was opened on April 18th in the presence of a large gathering. The ceremony was performed by Mrs. Nosworthy who in the course of a short speech promised to provide a new operating table for the institution at a cost of about £40.

abundant therefore is the amount of laminated clot which it contains. Dr. Walsham also draws attention to the fact that the heart is often found to lie nearly transversely in the chest when there is an aortic aneurysm, apparently because it has been pressed into this position by the superincumbent weight of the aneurysmal sac.

An improved knowledge of pathology has shown the method by which nature attempts to cure an aneurysm and by following the clue thus given various forms of treatment have been adopted for aneurysms which are surgically inaccessible to the more simple plan of ligature. Foremost amongst these methods are the administration of gelatin or calcium chloride to increase the coagulability of the blood generally; acupuncture, electrolysis, or wiring to promote coagulation locally. These methods have been tried chiefly in cases of intra abdominal and intra-thoracic aneurysm and hitherto with so limited a degree of success as to show that some can be abandoned as useless, whilst others, with improved technique, may yet prove serviceable in cases which have been properly selected.

The injection of gelatin.—The method of injecting gelatin was first recommended by Lancereaux in 1897 who based his recommendation upon experiments made by Dastre and Floresco confirmed by Camus and Gley, that the injection of a solution of gelatin into the veins rendered the blood more coagulable. After reporting a single successful case in 1897 Lancereaux in 1898 brought forward the details of five other cases for three of which he claimed complete success whilst in the remaining two death took place, in one patient from rupture of the aneurysm and in the other from uræmia. He sums up the conclusions at which he has arrived in the following words:—

> Gelatin introduced into the subcutaneous cellular tissue penetrates into the blood which it renders *more* than normally coagulable, and, since the blood encounters two conditions favourable to coagulation in the sac of the aneurysm, viz. a slowing of its current and a vascular wall which is often uneven, a more or less abundant clot is formed which in time fills the sac. This clot ultimately shrinks, the pouch in which it is contained diminishes in size and disappears. If the clot softens the blood penetrates between it and the walls of the sac and the tumour is reproduced. Under such conditions fortunately, coagulation again takes place readily. Gelatin, therefore, constitutes an excellent therapeutic agent, which, if it does not cure aneurysms, at any rate favours the general process of cure.

Lancereaux has fixed experimentally the quantity of gelatin necessary to obtain a sufficient coagulability of human blood. It is 250 cubic centimetres of a saline solution containing two grammes per 100 cubic centimetres of gelatin and he has found by experience that several months are required to obtain satisfactory results and that during this period at least 12 or 15 injections are necessary. According to Huchard a 1 per cent. solution of gelatin is safer than a 2 per cent. and it is advisable to leave a clear interval of from eight to ten days between each injection. As a general rule it is not possible to introduce more than 100 cubic centimetres of the gelatin solution into the subcutaneous tissue without causing pain and even this amount should be injected slowly—over an interval of from ten to 12 minutes—in order to avoid discomfort and overdistension of the skin. A considerable swelling is formed at the point of injection but it subsides entirely in from six to 12 hours. The inner aspect of the thigh is found to be the most convenient place for the injection. The method of procedure consists is filling a sterilised glass syringe with 100 cubic centimetres of the gelatin solution made as follows: One ounce of gelatin, 131 grains of sodium chloride, and 50 ounces of sterile distilled water are put into a flask plugged with cotton-wool. The flask is allowed to stand an hour or two for the gelatin to soften and it is then heated in a water-bath until the gelatin is dissolved. The flask is afterwards placed in a steamer for an hour and is subjected to this treatment on three consecutive days.

Immediately before it is used the quantity to be employed (100 cubic centimetres) is again re-steamed. Every precaution is taken to secure complete asepsis not only of the solution but also of the skin of the patient and the instruments employed. The necessity for complete sterilisation of the gelatin is shown by the fact that two patients died from tetanus at Guy's Hospital whilst undergoing this method of treatment and it appears that commercial gelatin often contains tetanus germs. It is satisfactory to find that these germs are killed by boiling for three minutes and that boiling for this length of time does not affect the process of gelatinisation.

Iodide of potassium is given in ten grain doses three times a day concurrently with the gelatin injections and with it Guthrie Rankin[5] combines minim doses of a 1 per cent. solution of nitroglycerine whenever the tension of the pulse becomes excessive or when there are symptoms of angina. The nitrogenous elements of the daily dietary are also reduced to the lowest extent and the amount of liquid allowed is kept within very narrow limits. This method of treating aneurysms by the subcutaneous injection of gelatin is still upon its trial in cases of inaccessible aneurysm. It is by no means uniformly successful and it appears likely to fall into disuse.

Treatment by the introduction of foreign bodies into the sac.—When the aneurysm is small and is inaccessible to ligature without being surgically inaccessible and when there is only a small aperture so that the danger of embolism is diminished, attempts have been made to cause coagulation locally in the sac by the introduction of foreign bodies.

Acupuncture.—Simple acupuncture without the use of electric currents was adopted at first upon the suggestion of Velpeau in France and of Benjamin Phillips in England. It has been employed by Christopher Heath and Chauncy Puzey. Three pairs of sewing needles are introduced into the sac where each pair are made to cross. They are left in position until the fifth day and are then withdrawn. Although some satisfactory results were obtained by this method it is not likely again to be adopted.

Wiring.—In 1864 Murchison and C. Moore[6] of the Middlesex Hospital passed a fine trocar and cannula into a large aneurysm of the ascending aorta which was protruding into the second and third intercostal spaces. 26 yards of fine iron wire were introduced into the sac of the aneurysm through the cannula, the end of the wire being pushed home with a blunt trocar. The operation lasted one hour and no anæsthetic was given. The patient seemed much relieved at first but died from sepsis on the fifth day. The post-mortem examination showed that the sac was full of clot mostly post mortem, but Moore points out that there was firm adhesion between the fibrin inclosing the wire and the wall of the aneurysm, so firm indeed that the adhesion was inseparable without dissection and the mass of wire and fibrin together could only be removed by tearing it apart. Loreta[7] in 1885 was the first to apply this method to an abdominal aneurysm. He performed laparotomy and passed six feet of silvered copper wire into a large aneurysmal sac. The patient left the hospital ten weeks later with the aneurysm reduced to a hard, non-pulsating mass of the size of a walnut. He died three weeks afterwards from rupture of the aorta below the aneurysm. G. L. Hunner[8] collected all the cases of this operation, both thoracic and abdominal, which had been published up to 1900. The list contains 14 cases with three cures and 11 deaths. A necropsy was obtained in nine of the 11 patients who died and in all there was evidence that the presence of the wire had induced firm clotting within the sac. The cases which did best were those in which from five to ten feet of wire were introduced.

Several other aneurysms have been "wired" since this list was published. In one by myself[9] an attempt was made to improve the technique of the operation by the use of an ingenious instrument devised by my house surgeon, Dr. G. H. Colt. The apparatus was designed to introduce a known quantity of silver wire into the sac of an aneurysm with complete asepsis, a maximum of speed and a minimum of disturbance. The instrument "snagged" the wire and caused it to coil within the sac. The simplicity of the operation defeated its own ends for the instrument worked so easily that in two minutes and a half I introduced 80 inches of silver wire into the aneurysm with a clotting surface of 3·7 square inches. The patient survived the operation 50 hours, and at the post-mortem examination a loop of silver elimination soon begins to take place through the ordinary channels of absorption. The fluid which thus accumulates in the splanchnic area may be sufficient in quantity to lead to fixation of the diaphragm and moveable ribs, causing death by respiratory failure. Saline infusion in shock raises but cannot sustain the blood pressure.

Adrenalin, as has been shown, acts both upon the heart and the blood-vessels. It raises the blood pressure in every degree of shock, even when the medulla is cocainised and when it is absent, as in an animal which has been decapitated. But adrenalin is so quickly oxidised by the body tissues and by the blood that its effects are very temporary. The drug must therefore be given continuously and in excessive doses it stimulates the cardio-inhibitory mechanism, though the stimulation can be set aside experimentally by the injection of atropine.

A pneumatic rubber suit which can be inflated at will provides an artificial peripheral resistance which is capable of controlling the blood pressure within a range of from 25 to 60 millimetres of mercury and is a useful adjuvant to adrenalin in cases of advanced shock. By the continued use of artificial respiration, rhythmic pressure upon the thorax over the region of the heart, and the infusion of adrenalin, animals which had apparently been dead for fifteen minutes were resuscitated. By the same means with the addition of the rubber suit a patient who had been conventionally dead for nine minutes after an injury to his brain was partially resuscitated for 32 minutes and during this time exhibited a strong heart beat and was able to move his head. It is clear from these investigations that we are in a fair way to obtain a rational treatment for shock and collapse based, as all surgical advances should be based, upon a sound substratum of pathological knowledge gained by experiment.

THE LIGATURE OF ARTERIES IN THEIR CONTINUITY.

Everyone who knows anything of the history of surgery knows that the modern method of stopping bleeding by the ligature of arteries is due to the labours of Ambroise Paré. The ligature of arteries was described by Celsus in A.D. 50 and by Galen in A.D. 130 and these surgeons recommended that the artery should be tied in two places and afterwards divided. Few people are aware of the amount of careful experimental work which has been performed to bring up the surgical technique of ligature to its present standard of excellence, though every surgeon knows the radical change of procedure which has taken place within the last 20 years. Then, a septic ligature passed round an artery was deliberately left with the ends hanging out of the wound that it might ulcerate through the vessel with a serious risk of secondary hæmorrhage; now, a thin ligature of silk or of some animal tissue capable of being absorbed is cut short after it has been tied and is buried in the wound in full confidence that it will become disintegrated, and secondary hæmorrhage is almost unknown.

In England many of the advances in our knowledge are due to the work of Ballance and Edmunds who published their conclusions in 1891.[2] The scientific portion of the work deals with the physiological occlusion and the pathological obliteration of arteries as illustrated by the ductus arteriosus and by the changes taking place in syphilitic arteritis. Consideration is given to the conduct and fate of the corpuscles, of the clot, of the arterial coats and of the ligature after an artery has been tied. The choice of ligature and the kind of knot are then discussed, together with the amount of force which should be exerted in tying the ligature. The most important practical points are those connected with the choice of ligature, the character of the knot, and the force employed. A perfect ligature must be sufficiently strong not to break: inelastic, round, smooth, pliable, and easily tied into a knot. It must not be too bulky; it should be capable of being absorbed, though not too readily. Lastly, a good ligature should be capable of being rendered absolutely sterile. These conditions are only fulfilled by a few materials and the choice of ligature must fall on ox peritoneum, gold-beaters' skin, kangaroo tendon or boiled floss silk; failing these on boiled Chinese twist silk, chromic catgut, or silkworm gut. The reasons for arriving at this conclusion as regards the nature of the ligature may be given in the following terms: "The outer coat and sheath of an artery consist of white fibrous tissue, and the most appropriate ligature, therefore, is prepared from this material—that is to say, from tendon or peritoneal tissue of sufficient strength. These ligatures satisfy all theoretical requirements. They are strong, inelastic, round, smooth, pliable, and are easily obtained of the proper size. They are slowly absorbed and are readily made aseptic. Peritoneum should be better than tendon because it resists absorption for a longer time. Floss silk is a smooth and trustworthy ligature. Ordinary silk and chromicised catgut are good, but their rough surfaces and the presence of mucous and muscular tissue in the catgut are defects, for it makes them more difficult to keep aseptic. Wire is too rigid and too difficult to handle to make it useful as a ligature; silkworm gut is not easy to manipulate round an artery unless it has been soaked for a long time in water and, moreover, several strands must be employed to make a ligature which will not cut the coats. This adds to the difficulty, but when these obstacles are overcome silkworm-gut makes a very beautiful ligature. Ox aorta must be rejected on account of its weakness, bulk, and elasticity." For the practical purposes of everyday life in the operating theatre I prefer silk for the ligature of arteries and I direct that it shall be unwound from the wooden reels on which it is bought, re-wound on glass reels in shorter lengths, and then boiled for at least an hour. I have an abiding distrust of catgut, even when it is most carefully prepared, and I think that when tendon is used the first half-hitch of the reef-knot is likely to slip whilst the second turn is being made.

The knots ordinarily used for tying ligatures are the reef, the granny, and the surgical knot. All are open to the objection I have just mentioned, that the first part of the knot may slip whilst the second part is being completed. There is thus "an uncertainty of occlusion" which applies not only to the tying of arteries but to the ligature of other structures, such as hernial sacs, and the pedicles of tumours. To overcome this difficulty Ballance and Edmunds recommend the use of two ligatures passed round the vessel and tied as a "stay knot." They make out a strong case both on experimental and clinical grounds for the discontinuance of the ordinary practice of rupturing the internal and middle coats of arteries when they are tied in their continuity. They advocate the occlusion of the lumen by bringing the intima into apposition for some distance at the seat of ligature. The great disadvantage attending rupture of the internal and middle coats as it is usually practised in the ligature of an artery in its continuity is that the vessel is seriously weakened. There is consequently a danger of secondary hæmorrhage and this accident has actually happened after ligature of large vessels like the innominate even when there has been no appreciable sepsis.

ANEURYSMS TREATED BY METHODS OTHER THAN LIGATURE.

Much has been done of late years by physicians to treat aneurysm successfully without having recourse to the surgeon. Bellingham's rest and diet method, advocated by Tufnell, combined with the administration of potassium iodide in ten grain doses every eight hours sometimes makes a new man of a patient with an aneurysm and enables him, at any rate for a time, to perform his duties again. But the relief is too often only temporary and in other cases it never occurs. Such desperate cases drift into the surgical wards of hospitals and it is then our endeavour to do by art what nature has failed to carry out.

Diagnosis by the Roentgen rays.—Dr. Hugh Walsham[3] in England and Dr. Guido Holzknecht[4] in Vienna have shown that the diagnosis of deeply seated thoracic and cardiac aneurysms is sometimes greatly assisted by the use of the screen and by radiographs. Dr. Walsham points out that to establish the diagnosis of an intrathoracic aneurysm the shadow must be in continuity with the heart or aorta and that the shadow of an intrathoracic new growth is quite different from that of an aneurysm. The variation in density between the heart shadow and the shadow of an aneurysmal sac is important from the point of view of prognosis. Fluid blood is almost completely transparent to the Roentgen rays, whilst laminated clot is comparatively opaque. The greater the density of the aneurysmal sac in the radiograph the more external tumour parallel to each other and one or two inches apart. The number of needles may be multiplied if the aneurysm is large and the action may be prolonged till pulsation ceases or till gas can be clearly detected on percussion. A séance of 20 minutes is generally enough for one application and this may be repeated according to the circumstances of the case. The method of simple electrolysis has yielded good results, even though they were only temporary in several selected cases, but of late years it has given place to a combination of wiring and electrolysis which is now known as—

The Moore-Corradi method.—Professor Corradi, the accomplished professor of the history of medicine at Pavia, suggested this combination of wiring and electrolysis to Professor Burresi[11] who employed it in a case of aneurysm of the ascending aorta in 1878. Barwell[12] suggested a treatment on similar lines independently of Corradi and the plan has since been followed up in America chiefly by D D Stewart.[13] The advantages claimed for the method are that instead of a soft unstable coagulum being slowly formed about the wire, as is the case when wiring alone is employed, electrolysis almost immediately produces a tough clot of considerable size. Experience has shown that the strength of the current must be rather high—from 40 to 80 milliampères—and the séance long—from three quarters of an hour to one and a half hours. It is better, too, not to have both poles in the aneurysm, as was formerly the custom, but the anode or positive pole should always be the active electrode. This pole is connected with the wire which has been previously introduced into the sac and the negative rheophore should be a large clay plate or pad of absorbent wool placed upon the abdomen or under the back. The current is brought into circuit slowly, its strength being noted by an accurate milliampère meter. It is gradually *increased for a few* moments until the maximum strength supposed to be necessary for the individual case is reached, and this *maximum is* then maintained until nearly the end of the séance, when it is slowly reduced to zero. Dr. Colt has adapted his apparatus to this method of treating aneurysm by providing the ramrod with a binding screw by which the positive pole of a battery can be brought into electrical communication with the end of a wisp previously introduced into the sac of the aneurysm Hunner[14] says that with the combined method (Moore-Corradi) there have been treated 23 cases, 17 thoracic and six abdominal. Four of these, or 17 per cent, three thoracic and one abdominal have been cured; nine cases, or 39 per cent, showed amelioration of symptoms and prolongation of life. Death was probably hastened in the other ten cases.

The Venous System.

It is difficult for us in 1905 to picture to ourselves the fear and abhorrence which surgeons felt towards any operation on the veins even so late as 1883. The third and last edition of Holmes's "System of Surgery" published in that year says (vol iii, p. 170) "Numerous operations are in use for the obliteration of varicose veins. They seek either merely to produce coagulation in the varix, to divide the venous channels above or below the varices, or, finally, to remove the varicose part of the vein These results can be obtained, firstly, by the action of caustics applied over the course of the vessel; secondly, by subcutaneous division of its walls; thirdly, by compressing it between a steel pin and a twisted suture or by some similar contrivance; or, lastly, by complete excision. Except in the cases which have been referred to these operations are not to be recommended and the patient, if wise, will be content with the palliative measures of a more simple character" In England Mr. John Marshall, surgeon to University College Hospital, gave a clinical lecture in 1874 on a Case of Varicose *Veins* Treated by a New Operation He advocated in this lecture that a considerable length of the veins should be excised where it is most enlarged and the operation was performed in the following manner "The course of the vein having been marked with ink, a pin is passed under it at each end of the part to be removed The limb is then emptied of blood by Esmarch's bandage, the skin is divided along the marked line, and the vein, previously secured by figure-of-eight ligatures passed over the pins, is cut across at each end and dissected out. The wound is then dressed after Lister's method." This lecture, published in THE LANCET of Jan. 23rd, 1875, p. 113, marks the first public recognition by hospital surgeons in England of the treatment of varicose veins by open incision, and it was not long before operations upon varicose veins became more numerous.

I find that at my own hospital—St. Bartholomew's—ten patients only were submitted to operation for the relief of varicose veins in 1875 and 12 in 1876 The results do not seem to have been satisfactory, for in 1877 only three cases are recorded and in 1878 five cases. The average number of cases admitted in the decennium 1875–1885 was 8·2 and in the years 1886–1893 it was 19. *After this year the numbers* increased rapidly and an average of 70 cases a year is now maintained.

The increasing confidence of surgeons in Listerian methods soon brought about modifications in the original operation. The underpinning of the veins was first omitted because it was not found necessary to make any attempt to limit the process of clotting and with aseptic wounds veins proved themselves as amenable to ligature as arteries.

The number and extent of the incisions necessary in an advanced case of varicose veins long militated against the success of the operation and a great step in advance was made by Trendelenburg in 1890 when he published his paper Ueber die Unterbindung der Vena Saphena magna bei Unterschenkelvaricen, from the surgical clinic at Bonn in the *Beiträge zur Klinischen Chirurgie*, vol. xvii. The operation recommended by Trendelenburg is so short, simple, and effective that I have been greatly interested in it and I have done various comparative operations in cases where the two legs have been pretty evenly affected. The results have been equally satisfactory on the two sides so far as I could get the patients to make definite statements They preferred, as was natural, the operation in which there was but a single scar and with this conclusion no surgeon could quarrel, for multiple wounds mean multiple chances of sepsis. Trendelenburg's operation, however, like everything else, has its limitations. *In my hands it* has not been of use in cases of extensive capillary varicose veins where the whole leg is mottled from the thigh to the foot, as so often happens in young women, neither have I been satisfied in cases where there have been only one or two greatly *enlarged veins, for* in these cases the trunks have remained full of blood which has shown no tendency to clot or to disappear.

[Mr. Power then made a few remarks upon the modern accepted methods of treating varicocele, hæmorrhoids, and nævi, and concluded as follows:—]

It is clear from this summary of recent surgical work in connexion with the vascular system that we have not reached a limit in any single branch. There is room for improvement in the *treatment of shock*; the method of ligaturing the larger arteries is by no means perfect; the cure of aneurysm is still at fault, and even nævi cannot yet be treated satisfactorily But neither has surgery itself attained to finality. Hosts of surgeons in every part *of the* world are enlarging its bounds and amongst them not a few are engaged in endeavouring to perfect the technique *of the* surgery of the blood-vessels.

A PAPER ON

HOSPITAL SHIPS AND THEIR WORKING IN WAR AND PEACE.

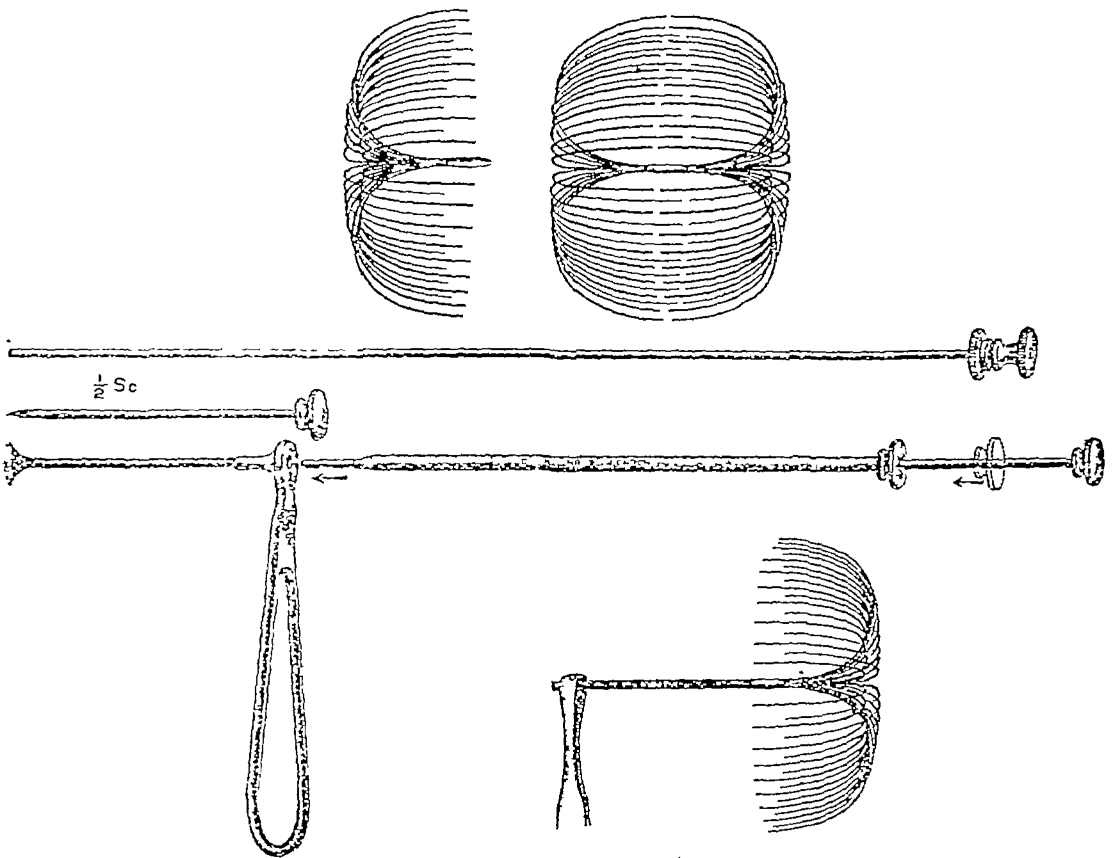
Read before the Section of Colonial and Naval Medicine of the Fifteent International Congress of Medicine, at Lisbon, April 19th to 26th, 1906,

BY P. B. HANDYSIDE, M.B., C.M. EDIN,
FLEET SURGEON, R.N.

THAT hospital ships are a necessity in time of war is now generally recognised but I would also urge *that* they are necessary in time of peace—that is to say, that ships should be built and fitted for this purpose, should be commissioned and should accompany every squadron in all its larger movements. Preparedness in this *matter is, I think*, greatly to be desired; unpreparedness seems to me to be merely courting trouble, if not disaster.

When war breaks out, as it may without much warnin wire seven inches long was found projecting into the arch of the aorta, the rest of the wire being coiled irregularly within the sac of the aneurysm and covered with blood clot, some of which was certainly formed during the life of the patient. The aneurysm was thought to be formed on one of the branches of the cœliac axis but the necropsy showed that it was derived from the abdominal aorta, that it was of the size and shape of a large orange, and that it projected forwards between the layers of the transverse mesocolon.

The apparatus consists of a trocar and cannula, a ramrod, a cartridge, and a wisp. The wisp consists of a number of fine steel wires soldered together at one end, each wire being curled over in a separate plane so that they readily expand as soon as they are at liberty to do so, though under ordinary conditions they are packed up into small bundles in which the wires lay parallel to each other. If it be preferred a cage can be used instead of a wisp. The cage consists of a bunch of fine steel wires caught together with solder at their midpoints, so that when the wires expand the cage becomes spherical. Both the wisps and the cages are made in different sizes to suit different aneurysms. Each wisp or cage fits into a cartridge or hollow metal tube open at both ends which can be adapted with ease and accuracy to the distal end of the cannula. The cartridge just holds the wisp or cage in its compressed condition as a bundle of wires lying side by side. When the operation is performed the sac of the aneurysm is exposed and if possible a purse string suture is run round the spot to be punctured. The trocar and cannula are driven through the sac wall, the trocar is withdrawn, and the cartridge containing a cage or wisp is fitted to the cannula. The contents of the cartridge are then gently pushed along the cannula by means of the ramrod until the wisp or cage is safely delivered into the sac of the aneurysm. The cannula and ramrod are immediately withdrawn and the purse-string suture is simultaneously tightened and tied to close the puncture. When a wisp is used care should be taken to puncture the sac in a direction which, as far as possible, is estimated to be towards the plane at its opening, because the wisp expands and curls back directly it begins to emerge from the cannula and there is consequently less danger of any of the wires projecting through the opening. When a cage is employed it will probably adapt itself better to the larger sac if the puncture be made in a direction parallel to the plane of the opening. Dr. Colt claims for his instrument, and I think he claims justly, that it abolishes the three great dangers attending the wiring of an aneurysm—viz., sepsis, hæmorrhage, and the escape of some of the wire from the aneurysmal sac into the parent artery. The older method of tediously introducing a length of wire into an aneurysmal sac through the lumen of a small cannula necessarily led to a serious risk of septic infection and there was a considerable loss of blood when the operation was prolonged. Dr. Colt's apparatus enables the operation to be performed in a few seconds and the whole apparatus can be thoroughly sterilised by boiling. It has been used three times within the last few months and in every case the surgeon has expressed his complete satisfaction with the manner in which it worked. The apparatus is fully described and illustrated in THE LANCET of Sept. 19th, 1903, p. 808.



The essential parts of the apparatus.

Electrolysis.—Galvano-puncture was originally suggested by Pravaz the younger, who was always interested in the treatment of aneurysm, for he took as the subject of his graduation thesis at Paris in 1857, "Sur le Traitement des Anéurysmes par les Injections de Perchlorure de Fer," and for making these injections he introduced the little Pravaz syringe, though it has long been divorced from its original purpose. Pravaz employed electrolysis for external aneurysms and in the form of galvano-puncture, but the method was soon taken up by Ciniselli[10] at Cremona, who used it in cases of thoracic and abdominal aneurysms, and he was followed by James and John Duncan in Scotland. For galvano-puncture of aneurysms steel needles are employed five inches in length, insulated to one and a quarter inches of their point. Four cells of a Bunsen's battery are sufficiently effective and do not give rise to more than a bearable amount of pain. The battery should have a continuous current and the needles, if this method of operating be adopted, should be introduced from the same side near the base of the should be capable of being brought directly over the operating table and there should also be a wandering lead with a reflector for use if operative procedure is required at night. Special arrangements for heating, in the way of extra pipes, should be fitted so as to insure a temperature of 80° F. if necessary. All the corners in the room should be rounded off; a tiled floor is preferable if it can be accurately laid, otherwise the floor should be covered with strong linoleum, the joinings of the different pieces being filled with putty or covered by thin strips of lead accurately laid and nailed down. Wooden gratings are required for the operator and his assistants to stand on so as to prevent slipping on a wet floor. The bulkheads and roof should be as smooth as possible and covered with several coats of white enamel paint. The operating table of strong and simple pattern should be on rubber wheels, but capable of being fixed in any position by locking of the wheels, or it might revolve on a central fixed pedestal with locking arrangements at four points; it is advantageous, I think, that the table should be moveable in some way in order that the part to be operated upon may be brought into the best light. Two metal screw-seat stools are required, one for the anæsthetist and the other for the operator in performing such an operation as that for hæmorrhoids. Three tables are necessary for instruments, sponges, and anæsthetics; these should all be trough-topped and have rubber wheels such as are on the operating table, and by means of a rail-guard they (and the stools) should be made fast to one of the bulkheads when not in use at sea. Six covered galvanised metal jugs are required, of about one gallon capacity each, to carry sterilised water or lotions, and a covered galvanised bucket should be fixed under the operation table, three enamelled basins are also required.

---

[10] L'Elettrolisi e le sue Applicazioni Terapeutiche, opera postuma del Dottor Ciniselli Cav. Luigi, compilata dai dottori Ottoni Cav. Gregorio e Omboni Vincenzo, Cremona, 1889.

The preparing room should communicate directly by a lift with the surgical ward; it should contain the instrument cases fixed to the bulkheads, case for anæsthetics, &c., wheeled table or ambulance for conveying patients from the lift to the operation table, basins for the operator and his assistants to wash in, and a sink; the drain-pipe from these basins and sink should not pass into any latrine pipe but directly overboard. The metal cases of sterilised dressings, aprons, gowns, &c., should be kept here as well as the steriliser for instruments.

8. *X ray room.*—All the apparatus necessary for x ray work should be placed in this room and closely fitting dark screens should be attached to the shutters of the scuttles. A small annexe should be fitted as a photographic developing room. The x ray room could also be used for ophthalmoscopic examinations.

9. *Bacteriological room*.—The bulkheads of this room should be fitted with racks for the various bottles and plant generally. The incubators should be easily removeable for cleaning, the microscopes also. Taps for hot and cold water are required and a sink.

10. *Dispensary.*—The dispensary for the compounding and issue of the drugs in daily use is best situated near the medical ward. All the drugs and chemicals should be in locked racks, the dispenser having one set of keys and a spare set kept by the medical officer in charge. This room should be especially well lighted by electricity; a wandering lead is necessary. On the lower deck, or below that, there should be a large dispensary store, also well lighted, provided with a table and weighing machine, and special arrangements must be made in the form of slate or earthenware tanks for the storage of strong chemicals and inflammable drugs, the jars containing which being placed in the tanks and packed round with asbestos.

11. *Repairing room*.—This is a most necessary adjunct, as the surgical instruments constantly require resetting and sharpening, and not only those of the hospital ship but also those of the various men of war. Lathes with grindstones are required and a complete set of implements. A qualified instrument-maker should be in charge.

12. *Dental room.*—A small room is required for dental work; good light, both natural and artificial, is necessary. Fixed cases are required for the instruments and the principal fittings are a dentist's chair and a dental engine; the latter could be worked from an ordinary electric fan by removing the blades.

13. *Store rooms.*—Such space as may be available on the lower deck might be utilised for medical stores—i.e., ward necessaries—and further provision should be made for these in the holds as required.

14. *Boats.*—For the removal of patients from a man-of-war special boats are required. These should have a deck-house, occupying the whole space, except a gangway all round, and projecting above the gunwhale about two feet: this upper part should have scuttles all round it for light and air and there should be a central hatch opening fore and aft to enable the cots to be let down easily; they should be capable of taking 12 cot cases and 12 others. These boats would be towed by steamboats, four of each being supplied to each hospital ship.

15. *Means for the transportation of cots.*—For the transportation of cot cases from the boats to the ward davits are required at each gangway and lifts from the upper to the main deck. There being three large hatchways from the upper to the main and lower decks, davits should be placed on the ship's side, both port and starboard; cots would thereby be brought to the upper deck, carried at once to the hatchway opposite them, and thence sent below by the lifts. The clearing of boats would thereby be facilitated and the patients got below as rapidly as possible.

CABINS AND WARDS FOR OFFICERS AND MEN.

A. *Officers.*—About 25 beds in all are required for officers. It is unnecessary that each officer should have a cabin to himself, as the difficulty of administration would thereby be increased; there should be five or six single-bed cabins for special cases, a four- or five-bed cabin for warrant officers, and the rest of the accommodation divided into a ward for officers confined to bed and one for those able to get about. In all cases swinging cots should be used and not bunks, in order that the patients may be approached from either side. Mosquito nets, bed-tables, &c., should be provided, as in the general wards, and in each single-bed cabin some kind of a fixed table is required, a chest of drawers, and a chair and a washstand.

B. *Men.*—The general arrangements of the medical and surgical wards should be practically the same. Sufficient space should be left amidships under the central skylight for mess tables and forms. The swinging iron cots should be arranged in parallel rows, fore and aft, in one tier, and slung from iron uprights, but for use in war time if necessary spare cots could be carried in the hold to be placed in a double tier in the wards as required. Each cot should be fitted with a wire basket for holding a handkerchief or books, and there should also be a light table capable of being placed across the cot or of lying parallel with it when not required. Mosquito curtains should be provided for each cot and a certain number of plain white curtains to act as screens if required; these should not be hung from the roof, as such a fitting would interfere with ventilation and with a second cot being placed overhead, but from iron rods supported by uprights attached to the sides of the cot, and in the event of a second tier cot being slung the curtains of the lower might be attached to the bottom of the upper. Lockers for clothing should be placed round the bulkheads with numbers corresponding to the cots. All the scuttles in the hospital accommodation should be provided with wire gauze screens, so that should the draught be too great it may be modified without the necessity of closing the scuttle.

The electric light should be controlled in groups by key switches in charge of the second sick-berth steward on duty and the globes should be fitted with a moveable screen so as to prevent direct glare into patients' eyes; four wandering leads are required in each general ward and these should be fitted with concave lateral reflectors and have switches of their own. Electric fans should be supplied for use in the scuttles or ventilating shafts and two strong iron moveable pedestals for each general ward to support a fan if it is necessary to direct a current of air on to a patient directly. The roofs and sides of the wards should be painted with white enamel and the floor planed as smooth as possible, then stained and polished. If possible, in each ward there should be a shelf for books. Electrically heated kettles are necessary for each general ward and one for the officers in their pantry. Ice chests are also required for each ward and there should be an aerated water machine as well.

In the surgical ward special cots for fracture cases should be placed in groups by themselves and with extra space all round them, so as to be readily got at from every side. Three dressing tables are required, on wheels, one for the dressings themselves in their various sterile metal cases, another for lotions and instruments, and a third, in some such form as a covered slop pail, for soiled dressings. In both medical and surgical wards there must be a locked cupboard for medicines.

what an amount of trouble and anxiety would be saved if, instead of having to select ships and have them fitted as hospitals, thoroughly equipped hospital ships were already with each squadron. Then, time occupied in fitting out such ships is also of great importance; the Japanese certainly did this in the case of the *Saikio Maru* and the *Kobé Maru* in a fortnight, but I doubt if any other nation could do it in anything like this time or as efficiently and the chances are that many details might be overlooked and the ships sent to sea insufficiently equipped. Every naval officer knows that a newly commissioned ship is not so efficient as one in which the *personnel* has had time to become acquainted with the *matériel*, and certainly this would be no less so in the case of a hospital ship. Also, suppose a great battle, as is highly probable, is fought at the very outbreak of war, how fearfully handicapped a fleet would be, more especially if victorious, in having to look after all its wounded as well as many of the enemy's; how space would have to be taken up for their treatment below decks; and how, in the absence of sufficient light and air, to say nothing of comfort, a serious risk would be run of lives being lost which would otherwise be saved.

In the construction of a hospital ship the following points present themselves for consideration: (1) Kind of vessel required and size; (2) disposition of accommodation for (*a*) sick officers and men, and (*b*) officers and crew of ship; (3) ventilation and heating; (4) sanitary arrangements; (5) laundry arrangements; (6) ice making and cold storage; (7) operation room; (8) x ray room; (9) bacteriological room; (10) dispensary; (11) repairing room for instruments; (12) dental room; (13) store rooms; (14) boats; and (15) means for transportation of cots.

1. *Kind of vessel.*—A hospital ship should be capable of accommodating not less than 200 cases; this means that the ship should be about 8000 tons. There should be a deck-house running from nearly right aft to five-sixths of the distance forward; a main deck principally for the accommodation of the sick and a lower deck for other cases and for the accommodation of the sick berth staff and the crew. On each side of the deck-house there should be a wide alleyway extending to the ship's side and covered by wooden planking, forming a flying deck for the housing of boats and providing a shelter for convalescents or for the open-air treatment of pulmonary cases. It is important that a hospital ship should have speed so that she can keep up with the fastest cruiser of a squadron and also be able to make trips to port and return with as little loss of time as possible. The height between decks (main deck) should not be less than eight feet.

2. *Disposition of accommodation: upper deck, from aft forward.*—Abaft all there should be a small mortuary and post-mortem examination room, having a cemented floor and with the sinks discharging by special pipes. On both sides of the ship aft lavatories and bathrooms should be fitted for the officers of the ship and in front of these, placed amidships, there should be a large hatchway leading to the main and lower decks. Immediately in front of this the deck-house should begin in which should be cabins on both sides for officers of the ship, a saloon forward of these to occupy both sides, a pantry, and a smoking-room for ships' officers on one side and one for convalescent officers on the other. Succeeding these should come the main hatchway leading to both main and lower decks. In front of the hatchway, alongside the funnel-casing, the cooking galleys might be placed one on each side, and after these rooms for bacteriological, x ray, and dental work, succeeding these a room for the repairing of instruments, the preparing room, and in the foremost part of the deck-house the operation room. The fore hatchway should be placed well in front, and beyond that, in the bows of the ship and quite separate from the deck-house, the soiled linen room, washing room, disinfecting room, and laundry.

Main deck, from aft forward.—In the after part the baggage rooms might be placed next a saloon for sick officers on one side and the library on the other, the passage way being on the same side as the latter. Succeeding these should come the cabins for sick officers on either side, and amidships, separated by a passage from the cabins, linen rooms and utensil rooms might be placed. Ahead of these, on one side, the pantry, latrines, and bath rooms for sick officers might be placed, similar accommodation for men being on the other side. Succeeding these should come the general medical ward extending from side to side of the ship. Forward again of this might be the dispensary amidships, on the port side a smoking-room for men and pantries and on the starboard lavatories and bathrooms. On each side amidships here the lifts from the cooking galleys would come down, and such space as is not required for them could be used for linen cupboards, &c. Forward of these the general surgical ward might be placed, extending, as in the medical ward, from side to side of the ship and communicating with the preparing room above by a lift. The fore hatchway would be placed next, and beyond this the special cabins for zymotic cases with their own latrines and bathrooms on one side and on the other, separated by a dividing bulkhead, cabins for special cases.

Lower deck.—Special accommodation would here be provided for the sick berth staff and for the ship's company, with corresponding latrines and bath arrangements. Two cabins for lunatics should also be placed here and other cabins for special cases as required, the rest of the space being taken up by store rooms, &c.

3. *Ventilation and heating.*—Ventilation throughout should be by natural means as far as possible, but for use in hot weather there should be a liberal supply of electric fans, the number provided having a due regard to the size of the space in which they are to be used. The cabins, bathrooms, &c., on the upper deck will be sufficiently ventilated by their ports and doors, but the saloons and smoking-rooms should have overhead apertures (skylights), as should also the operating room, and there should be special uptakes from the galleys to the boat deck. The various cabins for sick officers and their lavatories on the main deck, besides having large scuttles, should have supply and exhaust ventilation through cowls on the upper deck, and the same applies to the general medical and surgical wards, and, in fact, to all the spaces on this deck as well as to the lower deck. The general medical and surgical wards in addition should have a large skylight running centrally over each. The cowls should be placed at intervals on the upper deck and communicate by pipes leading overhead and along the floor deck respectively to each cabin, a means for closing (shutter) being fitted to each of the inlets so that in stormy weather too much draught is not set up.

The ship should be heated throughout by steam-pipes running along the sides in the case of the main and lower decks and amidships in the upper deck cabins; radiators should also be fitted in the general wards and two or more stoves, if a suitable uptake can be made for the chimneys. The steam-pipes should have their supply directly from the main boilers. Special means should be taken to insure the sufficient heating of the operating room, as the keeping of a patient warm does much to obviate shock during an operation.

4. *Sanitary arrangements.*—The number of latrines required is about 5 per cent. of the cases carried. There should be urinals in each set of water-closets, the receptacles being of thick glazed porcelain and not of metal, which is liable to accumulate a deposit and difficult, therefore, to keep clean; a free flushing by the sea-water should be assured in each case. Hot and cold water should be obtainable in the bathrooms at all hours. For the cleaning of bedpans and urinals there should be a special tap for the purpose.

5. *Laundry arrangements.*—The soiled linen should be collected in a special room on the upper deck forward next to the washing room; the washing is best done by steam-rollers, a centrifugal machine worked also by steam being used for getting rid of most of the water afterwards. It should then be passed into the disinfectors, dried by hanging on wooden "horses" which run in and out of a chamber, the atmosphere of which is dried by steam heat; it should then be mangled and ironed and conveyed to the special cupboards below. Such things as operating gowns, towels for operating room, &c., should be sterilised in their own metal cases and kept in these in the preparing room till required.

6. *Ice-making and cold storage.*—It is essential that ice be obtainable on board at all times and if it cannot be made in considerable quantities provision should be made for the carriage of it, not only for preserving food but for use in the general treatment of the sick; in any case cold storage is required. Ice chests for daily use should be provided in each set of wards.

7. *Operation room.*—This room seems to me to be best placed in the foremost part of the deck-house, that position insuring more light and a minimum of chances of dust or "blacks" from the funnels; it should be lighted by scuttles at the side and in front and overhead also. A + 30 electric light

it may be possible to obtain permission from the captain of the ship to use a casemate or screened-off part of the battery deck as an operation theatre, but there would be considerable difficulty in getting necessary arrangements made, and at the least the operator must run the risk of distractions from noise all around him, as unless the whole routine of the ship be brought to a standstill noise of some sort is certain to occur. The difficulties of sterilising, and keeping sterile, the dressings are great, and though the hands of the operator may be something like surgically clean those of the sick berth staff in attendance can hardly be expected to attain anything like this considering their multifarious duties; all this would be obviated if we had a hospital ship to which to send our cases.

Again, hospital ships in peace time could be used to great advantage: 1. For conveying patients or invalids to hospitals on shore when the squadron was at a distance; cases at present have often to be kept on board men-of-war for considerable periods on account of there being no means available for getting rid of them. 2. For conveying invalids home from foreign stations under the most favourable conditions as to accommodation, treatment, and supervision. 3. For taking to sea for short cruises or to more salubrious harbours patients from shore hospitals, for whom change is often a great desideratum. It often happens that there are cases (e g., pulmonary) in shore hospitals abroad when the climate is unsuitable, but who cannot be sent home, say, to face an English winter, and in these much good would surely be attained if they could be placed under better hygienic and climatic conditions. 4. For taking to more salubrious climates convalescents from home hospitals (e.g., Haslar to Madeira). There are many cases of disease (fevers) contracted abroad which, though improving under treatment at home, convalesce but slowly, especially during the winter and early spring, and it must not rarely happen that officers, but more especially men, cannot be allowed to go to their own homes during convalescence on account of the climatic conditions there being unsuitable for their complaints; in such cases it is surely to the advantage of the country that means be provided for securing to them the best prospect of a speedy return to health, such being also from a financial point of view the best in the long run. Also, if such arrangements as these were known to exist it would be an additional inducement, and not a small one, for both officers and men to join a service in which every care and attention were shown to those who contracted disease due to the conditions under which they were called upon to serve. 5. For instructional purposes. The hospital ships would provide excellent training for the surgeons and sick berth staff of the squadrons to which they were attached, and as from want of the opportunity for seeing cases most naval medical officers find it very hard to keep up their work in the constantly improving methods of treatment, here is one way at least in which this may be overcome. For the sick berth staff also this is most important.

I should like to see a regulation put in force by which medical officers and the members of the sick berth staff should, unless having served in a shore hospital within three years, serve in a hospital ship for six months out of every two years of their appointments afloat.

It may be said that if all the more serious cases are always to be transferred to hospital ships the medical staff of the warships will cease to take much interest in their professional work, but I do not think this will be so; no man who values his self-respect will become slovenly in this way merely because he has only minor cases to deal with; many a case trivial at first may become, as every medical man knows, most serious if proper attention be not accorded, and this of itself should be sufficient to deter a man inclined to "take things easy" from neglecting his duty. Also for the junior officers and the sick berth staff the knowledge that they must serve repeatedly in a hospital, whether ashore or afloat, where their abilities will be more highly tried and where the opportunities for the senior medical officers of observing their work will be much greater, will prevent them from becoming careless.

I have endeavoured to lay before you as succinctly as possible my ideas of the requirements of a hospital ship and what her functions would be in peace and war. I am quite aware my views are open to criticism on many sides, but it is only by bringing such views forward and submitting them to the criticism of those who understand the subject that a sound scheme for the establishment of hospital ships can be

REMARKS ON LEPROSY IN CAPE COLONY.[1]

BY ROBERT SINCLAIR BLACK, M.A. EDIN., M.D., D.P.H. ABERD.,

GOVERNMENT MEDICAL SERVICE, CAPE COLONY.

So much has recently been written on the subject of leprosy, it has been the occasion for so much discussion, that one almost needs to make an apology for introducing the question. The word "question" is, indeed, writ broadly all over what we know as to this ancient disease. Still, ancient, indeed prehistoric, as it no doubt is, leprosy is with us as a very present trouble. This is certainly the case with us in South Africa and to those visiting the country who are interested in disease the problems of leprosy in our midst present many features which must attract attention. It is, if not a burning question, one which may well be described as constantly smouldering, lighting up at intervals into periods of activity. The problems connected with it are not only pathological; there are administrative, legal, and even moral questions which arise out of its existence among us which need to be handled with great circumspection, moderation, and sagacity. One has only to turn to the map of the world to see how widespread the question is; it may almost be said that there exists hardly a British dependency or colony which has not its leprosy question. In India the patients approach in numbers 200,000, so great a multitude that the administration, skilled as they are in complicated social problems, are reluctant to put in force the necessary regulations for its control; while in Australia, small as is the number of the affected, alarm is felt at the insidious progress of the disease and vigorous measures to check its spread are being enforced. That such measures are urgent and necessary the history of leprosy in Cape Colony most clearly shows.

There are a number of countries in which we can with a very fair degree of accuracy trace the progress of leprosy within comparatively recent times. Such are some of the Pacific islands, Australia, some West Indian Islands, and the States of Central and South America, and among such countries we may fairly include South Africa. When the land was first colonised by Europeans towards the latter part of the seventeenth century the aboriginal races who met the invaders at the south-western extremity of the continent were the Hottentots and the Bushmen and I have been able to find no satisfactory evidence of any weight to show that leprosy was present among those races. It is true that some have stated that they were affected and not only they but also the Bantu race, who about the same time were pressing the more ancient inhabitants into the south-western corner of the continent. No satisfactory evidence is given of this either. We all know the rough-and-ready diagnosis of leprosy which is given to any cutaneous affection among savages by such untrained explorers as first came in contact with the natives of South Africa and little more weight is to be attached to traditions of disease among such native races. Besides, the very habits of these people precluded their being subject to this disease. The Bushmen were nomadic hunters, constantly moving from place to place in pursuit of game. The Hottentots were also largely wanderers, driving their flocks of cattle from one locality to another but never advanced so far towards settlement as to cultivate or to till the ground, and in this connexion it is to be noticed that those parts of the country which still retain the last pure remnants of those nearly extinct peoples are the parts which on the evidence of our statistics are practically free from leprosy. That the great incursion of the Bantus which resulted in the peopling of all the south-eastern parts of South Africa with that race brought leprosy in its train is in the highest degree improbable and unsupported by evidence of any value; the disease is not one to survive those long decimating campaigns, and the Bantus have always in their native state been remarkable for their attention to physique and for the extrusion by summary and effectual process of the chronic sick among them.

The spread of leprosy in this country has been from the south-west to the north east, following, indeed, the track of the new civilisation which has progressed in that direction.

---

[1] A paper read before the Physiological Section of the British Association for the Advancement of Science on August 18th, 1905.

In speaking of sterile dressing cases I should like to advocate that such things as sterile gauze, cyanide gauze, &c., should be supplied in rolls horizontally placed on revolving spindles in drum-like cases as nearly air-tight as possible and with the opening arranged valve-like at the side, so that just sufficient material could be drawn out as was required at a time, the rest remaining uncontaminated in the drum.

Some arrangement must be made for the collection and destruction of soiled dressings. They should be burnt, preferably in a destructor for the purpose, but if this cannot be conveniently arranged for, then in one of the main furnaces down below. The dressings as they are removed from a patient should be placed in paper bags, each of which would be closed by twisting its neck, and collected in the covered slop-pail and conveyed in it to the furnace.

The pantries for both the general wards should if possible be arranged at the ship's side opposite to where the lifts come down from the galleys. Sinks with hot and cold water are required and all washing of table crockery should be carried out here. Urinals and bedpans should be cleaned in a special water-closet in connexion with each set of latrines, where a jet of water can be applied from a special pipe for the purpose.

Wards for infectious cases.—These should be single-bed cabins; no special fittings are required but attention should be particularly directed to securing a hard, smooth surface to the bulkheads and floor, and to the position of the uptake ventilation on deck. For use in pulmonary tuberculous cases Japanese paper handkerchiefs should be supplied, into which the patients should be directed to expectorate; after use the handkerchief should be tightly squeezed and then placed in a covered metal pot, ultimately being burnt in the same manner as the surgical dressings. One or two hip-baths and portable water-closets are also required.

PERSONNEL.

A. *The medical staff in war time.*—One fleet surgeon as principal medical officer; one staff surgeon; four surgeons; one chief sick berth steward as butler; five first-class sick berth stewards: one for medical ward, one for surgical ward, one for officers' ward, one for infectious ward, and one for operation room, instruments, &c.; five second-class sick berth stewards: two for medical ward, two for surgical ward, and one as assistant dispenser; 25 sick berth attendants: nine for medical ward, nine for surgical ward, three for officers' ward, two for infectious ward, and two for special duty; one qualified dispenser in charge of stores; one instrument repairer; and four specially qualified cooks.

B. *The medical staff in peace time.*—One fleet surgeon as principal medical officer; three surgeons; one chief sick berth steward as butler; five first-class sick berth stewards as in war time; 15 sick berth attendants: six for medical ward, six for surgical ward, two for officers' ward, and one for infectious ward; one qualified dispenser in charge of stores; one instrument repairer; and two specially qualified cooks.

DUTIES AND WORKING OF HOSPITAL SHIPS.

A. *In war time.*—In time of war there should be at least two hospital ships to each squadron, or more, depending on the number of men-of-war constituting it. To one of these hospital ships the more serious cases occurring in the fighting ships should be transferred as often as opportunity occurs, so as to leave the latter unhampered and fit to engage the enemy at the shortest notice and in the most favourable circumstances. If this is not done such cases would have to be treated below-decks in their own ships, and the manner of doing so could not be other than unsatisfactory and with the great possibility of evil to themselves or, in the event of infectious cases, to others. They would also occupy space required for the accommodation of the injured in battle and their removal would leave the medical officers and sick berth staff free to devote all their energies to the wounded in battle.

Of course, in certain cases it might not be possible, from stress of weather or from the rapid movements of the squadron, to keep all the men-of-war clear of serious cases up to the time of an action, and probably there will always be some such on board, but still I think that every endeavour should be made to remove them in order that the fighting ships should be in as high a state of efficiency as possible.

I should in the above way fill up one hospital ship at a time, the other, or others, being kept for the emergency of battle. A certain number of these cases would probably return to their own ships cured, but this altogether depends on the nature of their complaints and the time which elapses between their reception on board the hospital ship and the battle. When full up or nearly so the hospital ship should be sent to the nearest hospital ashore and there discharge her sick, renew her supply of stores, and rejoin her squadron as soon as possible.

On an engagement taking place, whether of a running nature or of opposing squadrons circling round each other, all that the hospitals ships could do would be to keep as clear as possible without losing touch. Should a man-of-war be disabled and not pressed by the enemy a hospital ship would then approach her and take the wounded on board, the whole crew, if the former were sinking, but in this case the uninjured would be transferred to another man-of-war as soon as possible after the fight was concluded. In the event of a ship of A fleet coming up with a totally disabled ship of B fleet, and it being necessary for the latter to strike her flag, I presume that a hospital ship of B fleet would still approach and receive the seriously wounded, the surgeons of the A ship probably supervising which cases should be permitted to go to the B hospital ship and which they considered should be made prisoners on account of their injuries being such as would not be likely to prevent their rejoining the fighting line in a short time. It is unlikely that any nation would wish to encumber itself with the enemy's seriously injured and therefore they would permit all such to go on board their own hospital ships.

At the conclusion of a battle I presume the hospital ships of the victorious fleet would go to the nearest of their own men-of-war first and remove the cases from her, then taking the other ships in rotation, always having regard to any signals which indicated that a ship was so damaged as to be in danger of sinking and proceeding to her assistance in that case first. After collecting the wounded the hospital ships would make all speed to the nearest of their own shore hospitals and having landed their cases rejoin their squadrons without loss of time. I do not know whether hospital ships would be allowed to land their cases at neutral ports, but if they were I suppose that the men who recovered from their injuries would be interned till the end of the war, those who were capable of bearing arms again at any rate. Further than what has been above mentioned, what would happen to the hospital ships of the defeated fleet is hardly possible to say, as everything would depend on how much damaged the men of-war were; certainly, if able to escape the latter would not wait to transfer wounded anywhere near the scene of the action; the senior officer would probably make signals ordering the hospital ships to pursue such course as was considered necessary.

Besides their purely naval function, the employment of hospital ships for the conveyance of military wounded has to be considered. The sick and wounded of a naval brigade landed for duty ashore would naturally be removed home, as necessary, by the hospital ships, but it would be necessary also to do the like by the military, and for this purpose there should be ships of the mercantile marine selected during peace time which can be speedily converted into hospital ships as required.

B. *In peace time.*—There should be one hospital ship attached to each squadron and one to each of the large home hospitals, the latter being used as will be stated later, and also acting as reserve ships for war time when they could be despatched at once to supplement those of the various squadrons. I think it well also that there should be a certain number of ships of the mercantile marine selected during peace time to be converted into hospital ships if required in war, the whole detailed plan for their conversion being made out and ready for application.

In peace time a hospital ship accompanying its squadron would be available for the treatment of all the more serious cases of accident and disease occurring in such squadron; they would then receive better attention than is possible in a man-of-war, air, light, and freedom from noise would be assured, infectious cases could be isolated, and lunatics would have accommodation suitable to their condition. Further, injuries could be treated aseptically, a condition which is rarely obtained and only with the greatest difficulty in men-of-war. Most of us in the Naval Medical Service have felt the very nearly insurmountable difficulty there is in obtaining asepsis for wounds when having to operate in a man-of-war; first and foremost the operation has most likely to be performed in the sick bay, a place used as a ward, dining-room and dressing-room for all kinds of cases;

than 500. With our large coloured and native populations we will be fortunate if we attain anything like an approximate success by the middle of the present century. It need hardly be said that there is no evidence whatever that this continuous extension of the disease, geographically and numerically, is due to any particular form of diet or racial, hereditary, or climatic tendency. In all the circumstances fish, cured or uncured, fresh or unsound, or tainted or manipulated in any conceivable way, is about the last cause one would pitch on in South Africa as affording an explanation. One only needs to travel among the natives of the upland regions to be convinced of this; the facts were, indeed, too strong even for Mr. Jonathan Hutchinson, and to explain the communication of the disease to persons who clearly had never been exposed to fish contamination he conceived the "commensal" mode of communication, the disease being transferred from the affected to the healthy by food infected by leprous hands and thus conveyed to the body by means of the alimentary tract. This explanation, he contends, embraces all those cases of communication which cannot be explained by the assimilation of contaminated fish. This is certainly an enormous step on his part towards the admission of personal communication of the disease and yet even this lacks supporting evidence. When I was medical officer on Robben Island I had an opportunity extending to a period of seven years of examining the pathological conditions in a large number of necropsies of leprous individuals which were performed with some care, and I cannot recall a single case where the absorptive apparatus of the alimentary tract was the seat of leprotic lesions. This freedom was, indeed, very remarkable and unmistakeably pointed to the conclusion that this was not one of the channels by which the bacilli reached their nidus of growth in the body. Of course, in a bad nodular case bacilli must have passed down the canal in enormous numbers and yet the mesenteric lymphatic glands do not show leprotic invasion. Leprous ulcers, in my experience of the mucous membranes of the stomach and intestines, are never found. But in those cases where lepropsy is complicated with tuberculosis tuberculous ulceration of the intestines and infiltration of the mesenteric glands with the inflammatory reactive products of the tubercle bacillus were as common as might be expected. The difference in the action of the two bacilli was in this respect most marked, as it is indeed in so many other vital reactions, so much so, indeed, that it seems extraordinary to hear the suggestion made that a specific relationship exists between the two bacilli. Later I shall allude to some of the other remarkable selective activities of the bacillus lepræ, but here I may say a word as to the common combination of leprosy and tuberculosis in the same individual. The maculo-anæsthetic variety of leprosy is much more frequently affected with tuberculosis than the nodular and tuberculosis is the usual cause of death in this clinical form. But occasionally a nodular case may be infected by the tubercle bacillus and then the two diseases strive together for the destruction of the unfortunate patient, pursuing perfectly independent courses, and in point of rapidity of action and virulence the bacillus tuberculosis soon anticipates the bacillus lepræ in its lethal effect; it possesses the toxic power of causing coagulative necrosis in the cells surrounding it, a property entirely absent in the bacillus lepræ, its absence accounting for many of the peculiar characteristics of leprosy.

In the Colony the districts where the disease first made its appearance unmistakeably are still those where it is most abundant; Caledon, where the first leper hospital was established, still holds a bad pre-eminence, the proportion of the population affected amounting for all races to nearly 5 per 1000, a proportion which decreases radially in the surrounding districts of the western province. The thickly populated district of Stockenstrom in the eastern province, adjoining densely stocked native districts, is another area where the proportion of affected is nearly as large as in the west, and here also we notice the same radiating diminution in the surrounding districts Another region where the proportion is fairly high is that surrounding, and to the west of, Kimberley, where it is 2·5 per 1000. It will thus be seen that there are large districts in the colony where leprosy is endemic and that these districts differ from each other in geographical position, climate, and character of population; they agree in the considerable number of individual leprous foci they contain, and have for a long time contained. In a visit which I made in connexion with this subject in 1898 to the native territories I was particularly struck with the focal character of the distribution in those parts where it had not been for a lengthened period endemic. Leprous kraals, separated from each other by wide tracts, were frequently found. On inquiring into the history of such kraals the headsman of the district would not seldom give the information that a relative of the occupier had returned from working in some distant part of the Colony either leprous or after his return had become so, and that some time afterwards other cases made their appearance in the kraal.

The number of those of European descent on the register in 1903 amounted to close on 100 and of these six were born out of the Colony. While the great majority are of Dutch colonial descent, a proportion are of pure British extraction. Up till 1896 there were very few European lepers on Robben Island who were not of Dutch colonial descent, but since then an increasing number of pure British extraction have been admitted, some of them cases of great severity, and, with a few exceptions, these had, before coming to South Africa, visited countries where they might have contracted the disease; the others acquired it in the Colony. Of course, hereditary predisposition was in these cases out of the question, and in some there was an acknowledged history of association with lepers, not, however, amounting to "commensalism." The large preponderance of the European cases I have seen, and this is also borne out by statistics, have been of the nodular or mixed variety. The same variety is also in excess in Norway. Australian statistics also show the proclivity of those of European descent to develop the disease in this severe form. Why it should be so is difficult to say. On the other hand, the pure native, as seen in his own natural habitat, as a rule, develops the disease in the maculo-anæsthetic form and, more than this, many of them take it in a slight form and do not exhibit in its course that cachectic look which is so characteristic of actively progressive leprosy. Some of these natives show only a few insignificant maculæ, with perhaps in addition a contraction of the fingers and slight wasting of the arm muscles, often unilateral; they are frequently, apart from this slight disfigurement, quite healthy-looking and able-bodied. The infectivity of such cases needs very careful consideration and is receiving it at the hands of the responsible officials. Bad cases of nodular or mixed leprosy are of course met with among the natives and are apt to be very severe indeed. But, as I have said, the proportion affected in this way is comparatively very small. It has also seemed to me that leprosy tends to run a less severe and a modified course in the high and dry inland regions of the country and that the proportion of nodular cases increases with propinquity to the coast line. I have already mentioned a racial predisposition to a certain form of clinical affection in the disease and now it would seem that climate is not without some modifying effect.

Many of the maculo-anæsthetic cases are extremely prone to the attack of tuberculosis, and particularly so when confined in institutions, and a very large proportion of the annual leper death rate is due to tuberculosis killing off such cases. The nodular form seems much less susceptible to tuberculosis and it is difficult to find a satisfactory explanation of this unless it is due to the condition of general leucocytosis which is so prominent a feature in nodular leprosy. Indeed, but for the dying off of the patients from tuberculosis the accumulation of the affected would be very much greater than it is. In the mixed races the preponderance of the maculo-anæsthetic over the nodular cases is not so great, but the excess is nevertheless very considerable.

In most other respects the clinical history of affected persons in this country presents no difference whatever from what occurs in leprosy all the world over. It has the same insidious beginning, the same lack of definite information exists as to the time and source of infection. Considering that we know practically nothing about the incubation period of leprosy this uncertainty is not surprising; it applies, though in a less degree, to the sources of infection in individual cases of tuberculosis. The cases which one usually sees in asylums are comparatively old cases even on admission. I have examined close on 2000 cases on Robben Island, Emjanyana, the native territories, and various parts of the country, but I do not recall among them one who could with certainty be said to have been affected for a less period than 18 months, and the vast majority were much older. By the time a case becomes suspiciously recognisable it is by no means of very recent origin. The period of incubation of an infective disease is usually and properly

The earliest cases to attract attention occurred in the neighbourhood of the Cape Peninsula near the first settlement, Cape Town. During the early days of Dutch colonisation, when the Cape was under the control of the Dutch East India Company, many servants and slaves were brought from the East, from those very parts which had long been infested with leprosy. From the centre and hotbed of leprosy in the Far East, south-eastern China, it had been carried by the emigrating coolies all over the eastern archipelago to those very parts of the Dutch East Indies from which Malays and others were brought by the Dutch traders to their new colony at the Cape, and as even at that time the climate was noted for its healthfulness it is most probable that invalids suffering from tropical diseases settled in the Cape Peninsula. It is practically agreed on all hands that the leprosy in Cape Colony was introduced by Malays or coloured servants or slaves imported from the Dutch East Indies. Mr. Jonathan Hutchinson, indeed, has ventured to give a characteristic interpretation to this generally accepted account of the initial method of its introduction. He states that as the early Dutch farmers were unable to find food to supply their Hottentot labourers Malays were brought from the East for the purpose of salting and curing fish for a food-supply and that the badly cured fish was the means of conveying and disseminating leprosy and giving it the hold on the coloured population at the Cape which it has ever since increasingly maintained. But we know well from the history of Chinese- and Malay-introduced leprosy in Australia and elsewhere that such immigrants did not in all cases arrive for the purpose of curing or dealing in fish, and also that their dietetic and social habits were revolting rather than acceptable to the populations they were thrown among and yet that leprosy followed on their immigration.

As the new colony at the Cape became more settled and organised the intermingling of the various people transplanted from the East, from Java, Ceylon, Madagascar, and Mozambique, and other eastern lands, with the indigenous stock, has produced a heterogeneous and motley population of every gradation of colour, feature, and physique, and this constitutes the coloured or mixed race which from an early period, by its serviceable qualities, has been employed in all agricultural, domestic, and industrial duties at the Cape, and it is this class in the Colony proper, excluding the native territories, which shows the preponderating number of those affected with leprosy, and it is undoubtedly to this class that we must, in the first instance, attribute the passing of the disease to the healthy European settlers. Numerous instances are on record where the disease in a Dutch farmer's family seemed to have its origin in the presence of a leprous farm servant or domestic. The following authenticated and suggestive history is selected from many others submitted in evidence to the Leprosy Commission of 1895. Leprosy was first noticed on a certain farm in the Western Province in the case of a Hottentot labourer who had been working on it for a short time; next a little girl, the farmer's daughter, became affected; then the waggon-driver, a close intimate of the Hottentot, showed unmistakeable symptoms; then followed the farmer himself; then a girl who had come to nurse the farmer's daughter; and finally the farmer's niece who frequently visited the farm and who was intimate with the leprous daughter of the farmer became herself a victim to the disease.

In 1756 it was noted with alarm that the families of two European farmers in the Stellenbosch district were affected with leprosy and they were partially isolated on their own farms, but nothing further appears to have been done and the disease spread apace, causing serious anxiety to the Government in the early years of the nineteenth century, so much so that an asylum was set apart for sufferers. It was most prevalent in the Caledon district and then in 1822 the settlement was placed on a spot which by some grim irony was called Hemel en-Arde—heaven on earth. It was an isolated spot and patients were brought from long distances to it, for the disease had by this time become widely disseminated in the colonised area. From 1822 till 1845, when Robben Island was constituted the asylum, upwards of 400 cases were confined there. But the patients isolated at Hemel-en-Arde and at Robben Island up to the time the present stringent Leprosy Repression Act was inforced in 1892 were voluntary cases and doubtless therefore of the most severe and helpless kind, so that during that long period a far greater number must have been at large. The passing of the Act was the recognition that the evil had now assumed most serious proportions, leprosy was spread far and wide throughout the Colony, had obtained a firm hold of the dense native population in the Eastern Province, had invaded the native territories proper and crossed the frontier into the Orange Free State, the Transvaal, and found a nidus among the Zulus of Natal.

As soon as the Leprosy Repression Act was put in force it was evident that Robben Island would not suffice to accommodate all the affected, and a large asylum was established in a beautiful and fertile spot in the centre of the native territories at Emjanyana. Its inmates are now practically as numerous as those of Robben Island and the question of accommodation there is equally urgent. I may mention here in connexion with the spread of leprosy a factor which has materially contributed to it in the eastern region of the native territories. In 1862 the British Government allowed several thousand Griquas under Adam Kok to settle in that part of Kaffraria now known as Griqualand East. These were a race of mixed Dutch and Hottentot descent who had previously lived in the large district west and north-west of Kimberley. Leprosy is known to have been firmly established among them. They migrated to the number of 15,000 to a depopulated tract of country and founded the settlement of which the town of Kokstad is now the centre. Here a leprous focus was established from which the disease spread widely in that part of the country and for some years there has been a small asylum in the neighbourhood of the town. I happened to visit that district in 1898. An improvement has no doubt been effected since but the evidence of the prevalence of leprosy in that district and of its tolerance by the inhabitants at the time was such as to give rise to grave concern; it was evident that the disease had taken a firm hold and was viewed in a somewhat fatalistic spirit.

As indicating to some extent the increase and spread of leprosy in Cape Colony, though no doubt the figures are accentuated by a more thorough application of sanitary enactments, I may quote some statistics comparing the year of the census of 1891 with that of 1904. In 1891 there were 626 known lepers, and in 1904 1230, a very considerable increase in both Europeans and other than Europeans. The increase in the total leprosy-rate per 10,000 was 24 per cent., the European increase was 15 per cent., and in other than Europeans 25 per cent. The persons in the colony enumerated as leprous increased from 1891 to 1904 by 81 per cent., while the population increase was 57 per cent. The Hottentot and mixed races have the highest leprosy-rate, and the Europeans the lowest, while the Kaffirs at present occupy an intermediate position. Of the 1230 persons enumerated as leprous in 1904, 1087 were in asylums or other public institutions and 143 in private dwellings. On June 30th, 1904, 479 of them were segregated on Robben Island and 492 at Emjanyana, while six apparently were at the small station at Kokstad. The above figures for the colony do not include about 100 leprous persons from the Orange River Colony who are segregated at Robben Island. In the census report the matter is well summed up as follows: "There has been a decided increase in leprosy and it has not yet been adequately coped with for lack of asylum accommodation; many hundreds of the leprous die in their homes under no medical supervision or regulation. The medical officer of health of the colony estimated the number of lepers still at large in 1903 as at least 1000. Between 1893 and 1903, on an average 286 fresh cases have been discovered per annum without any very special endeavour to discover fresh cases, but only 190 per annum have been sent to asylums. There is no decided sign as yet of diminution of the number of occurring cases, notwithstanding the large numbers sent to the leper asylums." These are not very cheering figures for those who desire to see leprosy diminished to a vanishing point at no distant date; but when we learn from the report of the medical officer of health that the discovery of the leprous depends entirely on notification made by medical men and persons under whose observation they may chance to come, so that only well-marked cases are brought to light, the prospect seems still more remote. In the native territories especially, it is stated, "only some of the more obvious cases have been brought to notice."

Sufficient has now been said to show how from small beginnings the disease has spread over the country and become a most serious problem. The numbers in Cape Colony at present approach those existing in Norway in 1856 and it has taken half a century of segregation in a civilised and educated people to reduce that number to less than 500. With our large coloured and native populations we will be fortunate if we attain anything like an approximate success by the middle of the present century. It need hardly be said that there is no evidence whatever that this continuous extension of the disease, geographically and numerically, is due to any particular form of diet or racial, hereditary, or climatic tendency. In all the circumstances fish, cured or uncured, fresh or unsound, or tainted or manipulated in any conceivable way, is about the last cause one would pitch on in South Africa as affording an explanation. One only needs to travel among the natives of the upland regions to be convinced of this; the facts were, indeed, too strong even for Mr. Jonathan Hutchinson, and to explain the communication of the disease to persons who clearly had never been exposed to fish contamination he conceived the "commensal" mode of communication, the disease being transferred from the affected to the healthy by food infected by leprous hands and thus conveyed to the body by means of the alimentary tract. This explanation, he contends, embraces all those cases of communication which cannot be explained by the assimilation of contaminated fish. This is certainly an enormous step on his part towards the admission of personal communication of the disease and yet even this lacks supporting evidence. When I was medical officer on Robben Island I had an opportunity extending to a period of seven years of examining the pathological conditions in a large number of necropsies of leprous individuals which were performed with some care, and I cannot recall a single case where the absorptive apparatus of the alimentary tract was the seat of leprotic lesions. This freedom was, indeed, very remarkable and unmistakeably pointed to the conclusion that this was not one of the channels by which the bacilli reached their nidus of growth in the body. Of course, in a bad nodular case bacilli must have passed down the canal in enormous numbers and yet the mesenteric lymphatic glands do not show leprotic invasion. Leprous ulcers, in my experience of the mucous membranes of the stomach and intestines, are never found. But in those cases where lepropsy is complicated with tuberculosis tuberculous ulceration of the intestines and infiltration of the mesenteric glands with the inflammatory reactive products of the tubercle bacillus were as common as might be expected. The difference in the action of the two bacilli was in this respect most marked, as it is indeed in so many other vital reactions, so much so, indeed, that it seems extraordinary to hear the suggestion made that a specific relationship exists between the two bacilli. Later I shall allude to some of the other remarkable selective activities of the bacillus lepræ, but here I may say a word as to the common combination of leprosy and tuberculosis in the same individual. The maculo-anæsthetic variety of leprosy is much more frequently affected with tuberculosis than the nodular and tuberculosis is the usual cause of death in this clinical form. But occasionally a nodular case may be infected by the tubercle bacillus and then the two diseases strive together for the destruction of the unfortunate patient, pursuing perfectly independent courses, and in point of rapidity of action and virulence the bacillus tuberculosis soon anticipates the bacillus lepræ in its lethal effect; it possesses the toxic power of causing coagulative necrosis in the cells surrounding it, a property entirely absent in the bacillus lepræ, its absence accounting for many of the peculiar characteristics of leprosy.

In the Colony the districts where the disease first made its appearance unmistakeably are still those where it is most abundant; Caledon, where the first leper hospital was established, still holds a bad pre-eminence, the proportion of the population affected amounting for all races to nearly 5 per 1000, a proportion which decreases radially in the surrounding districts of the western province. The thickly populated district of Stockenstrom in the eastern province, adjoining densely stocked native districts, is another area where the proportion of affected is nearly as large as in the west, and here also we notice the same radiating diminution in the surrounding districts. Another region where the proportion is fairly high is that surrounding, and to the west of, Kimberley, where it is 2·5 per 1000. It will thus be seen that there are large districts in the colony where leprosy is endemic and that these districts differ from each other in geographical position, climate, and character of population; they agree in the considerable number of individual leprous foci they contain, and have for a long time contained. In a visit which I made in connexion with this subject in 1898 to the native territories I was particularly struck with the focal character of the distribution in those parts where it had not been for a lengthened period endemic. Leprous kraals, separated from each other by wide tracts, were frequently found. On inquiring into the history of such kraals the headsman of the district would not seldom give the information that a relative of the occupier had returned from working in some distant part of the Colony either leprous or after his return had become so, and that some time afterwards other cases made their appearance in the kraal.

The number of those of European descent on the register in 1903 amounted to close on 100 and of these six were born out of the Colony. While the great majority are of Dutch colonial descent, a proportion are of pure British extraction. Up till 1896 there were very few European lepers on Robben Island who were not of Dutch colonial descent, but since then an increasing number of pure British extraction have been admitted, some of them cases of great severity, and, with a few exceptions, these had, before coming to South Africa, visited countries where they might have contracted the disease; the others acquired it in the Colony. Of course, hereditary predisposition was in these cases out of the question, and in some there was an acknowledged history of association with lepers, not, however, amounting to "commensalism." The large preponderance of the European cases I have seen, and this is also borne out by statistics, have been of the nodular or mixed variety. The same variety is also in excess in Norway. Australian statistics also show the proclivity of those of European descent to develop the disease in this severe form. Why it should be so is difficult to say. On the other hand, the pure native, as seen in his own natural habitat, as a rule, develops the disease in the maculo-anæsthetic form and, more than this, many of them take it in a slight form and do not exhibit in its course that cachectic look which is so characteristic of actively progressive leprosy. Some of these natives show only a few insignificant maculæ, with perhaps in addition a contraction of the fingers and slight wasting of the arm muscles, often unilateral; they are frequently, apart from this slight disfigurement, quite healthy-looking and able-bodied. The infectivity of such cases needs very careful consideration and is receiving it at the hands of the responsible officials. Bad cases of nodular or mixed leprosy are of course met with among the natives and are apt to be very severe indeed. But, as I have said, the proportion affected in this way is comparatively very small. It has also seemed to me that leprosy tends to run a less severe and a modified course in the high and dry inland regions of the country and that the proportion of nodular cases increases with propinquity to the coast line. I have already mentioned a racial predisposition to a certain form of clinical affection in the disease and now it would seem that climate is not without some modifying effect.

Many of the maculo-anæsthetic cases are extremely prone to the attack of tuberculosis, and particularly so when confined in institutions, and a very large proportion of the annual leper death rate is due to tuberculosis killing off such cases. The nodular form seems much less susceptible to tuberculosis and it is difficult to find a satisfactory explanation of this unless it is due to the condition of general leucocytosis which is so prominent a feature in nodular leprosy. Indeed, but for the dying off of the patients from tuberculosis the accumulation of the affected would be very much greater than it is. In the mixed races the preponderance of the maculo-anæsthetic over the nodular cases is not so great, but the excess is nevertheless very considerable.

In most other respects the clinical history of affected persons in this country presents no difference whatever from what occurs in leprosy all the world over. It has the same insidious beginning, the same lack of definite information exists as to the time and source of infection. Considering that we know practically nothing about the incubation period of leprosy this uncertainty is not surprising; it applies, though in a less degree, to the sources of infection in individual cases of tuberculosis. The cases which one usually sees in asylums are comparatively old cases even on admission. I have examined close on 2000 cases on Robben Island, Emjanyana, the native territories, and various parts of the country, but I do not recall among them one who could with certainty be said to have been affected for a less period than 18 months, and the vast majority were much older. By the time a case becomes suspiciously recognisable it is by no means of very recent origin. The period of incubation of an infective disease is usually and properly

The earliest cases to attract attention occurred in the neighbourhood of the Cape Peninsula near the first settlement, Cape Town. During the early days of Dutch colonisation, when the Cape was under the control of the Dutch East India Company, many servants and slaves were brought from the East, from those very parts which had long been infested with leprosy. From the centre and hotbed of leprosy in the Far East, south-eastern China, it had been carried by the emigrating coolies all over the eastern archipelago to those very parts of the Dutch East Indies from which Malays and others were brought by the Dutch traders to their new colony at the Cape, and as even at that time the climate was noted for its healthfulness it is most probable that invalids suffering from tropical diseases settled in the Cape Peninsula. It is practically agreed on all hands that the leprosy in Cape Colony was introduced by Malays or coloured servants or slaves imported from the Dutch East Indies. Mr. Jonathan Hutchinson, indeed, has ventured to give a characteristic interpretation to this generally accepted account of the initial method of its introduction. He states that as the early Dutch farmers were unable to find food to supply their Hottentot labourers Malays were brought from the East for the purpose of salting and curing fish for a food-supply and that the badly cured fish was the means *of conveying and disseminating leprosy and giving it* the hold on the coloured population at the Cape which it has ever since increasingly maintained. But we know well from the history of Chinese- and Malay-introduced leprosy in Australia and elsewhere that such immigrants did not in all cases arrive for the purpose of curing or dealing in fish, and also that their dietetic and social habits were revolting rather than acceptable to the populations they were thrown among and yet that leprosy followed on their immigration.

As the new colony at the Cape became more settled and organised the intermingling of the various people transplanted from the East, from Java, Ceylon, Madagascar, and Mozambique, and other eastern lands, with the indigenous stock, has produced a heterogeneous and motley population of every gradation of colour, feature, and physique, and this constitutes the coloured or mixed race which from an early period, by its serviceable qualities, has been employed in all agricultural, domestic, and industrial duties at the Cape, and it is this class in the Colony proper, excluding the native territories, which shows the preponderating number of those affected with leprosy, and it is undoubtedly to this class that we must, in the first instance, attribute the passing of the disease to the healthy European settlers. Numerous instances are on record where the disease in a Dutch farmer's family seemed to have its origin in the presence of a leprous farm servant or domestic. The following authenticated and suggestive history is selected from many others submitted in evidence to the Leprosy Commission of 1895. Leprosy was first noticed on a certain farm in the Western Province in the case of a Hottentot labourer who had been working on it for a short time; next a little girl, the farmer's daughter, became affected; then the waggon-driver, a close intimate of the Hottentot, showed unmistakeable symptoms; then followed the farmer himself; then a girl who had come to nurse the farmer's daughter; and finally the farmer's niece who frequently visited the farm and who was intimate with the leprous daughter of the farmer became herself a victim to the disease.

In 1756 it was noted with alarm that the families of two European farmers in the Stellenbosch district were affected with leprosy and they were partially isolated on their own farms, but nothing further appears to have been done and the disease spread apace, causing serious anxiety to the Government in the early years of the nineteenth century, so much so that an asylum was set apart for sufferers. It was most prevalent in the Caledon district and then in 1822 the settlement was placed on a spot which by some grim irony was called Hemel en-Arde—heaven on earth. It was an isolated spot and patients were brought from long distances to it, for the disease had by this time become widely disseminated in the colonised area. From 1822 till 1845, when Robben Island was constituted the asylum, upwards of 400 cases were confined there. But the patients isolated at Hemel-en-Arde and at Robben Island up to the time the present stringent Leprosy Repression Act was inforced in 1892 were voluntary cases and doubtless therefore of the most severe and helpless kind, so that during that long period a far greater number must have been at large. The passing of the Act was the recognition that the evil had now assumed most serious proportions, leprosy was spread far and wide throughout the Colony, had obtained a firm hold of the dense native population in the Eastern Province, had invaded the native territories proper and crossed the frontier into the Orange Free State, the Transvaal, and found a nidus among the Zulus of Natal.

As soon as the Leprosy Repression Act was put in force it was evident that Robben Island would not suffice to accommodate all the affected, and a large asylum was established in a beautiful and fertile spot in the centre of the native territories at Emjanyana. Its inmates are now practically as numerous as those of Robben Island and the question of accommodation there is equally urgent. I may mention here in connexion with the spread of leprosy a factor which has materially contributed to it in the eastern region of the native territories. In 1862 the British Government allowed several thousand Griquas under Adam Kok to settle in that part of Kaffraria now known as Griqualand East. These were a race of mixed Dutch and Hottentot descent who had previously lived in the large district west and north-west of Kimberley. Leprosy is known to have been firmly established among them. They migrated to the number of 15,000 to a depopulated tract of country and founded the settlement of which the town of Kokstad is now the centre. Here a leprous focus was established from which the disease spread widely in that part of the country and for some years there has been a small asylum in the neighbourhood of the town. I happened to visit that district in 1898. An improvement has no doubt been effected since but the evidence of the prevalence of leprosy in that district and of its tolerance by the inhabitants at the time was such as to give rise to grave concern; it was evident that the disease had taken a firm hold and was viewed in a somewhat fatalistic spirit.

As indicating to some extent the increase and spread of leprosy in Cape Colony, though no doubt the figures are accentuated by a more thorough application of sanitary enactments, I may quote some statistics comparing the year of the census of 1891 with that of 1904. In 1891 there were 626 known lepers, and in 1904 1230, a very considerable increase in both Europeans and other than Europeans. The increase in the total leprosy-rate per 10,000 was 24 per cent., the European increase was 15 per cent., and in other than Europeans 25 per cent. The persons in the colony enumerated as leprous increased from 1891 to 1904 by 81 per cent., while the population increase was 57 per cent. The Hottentot and mixed races have the highest leprosy-rate, and the Europeans the lowest, while the Kaffirs at present occupy an intermediate position. Of the 1230 persons enumerated as leprous in 1904, 1087 were in asylums or other public institutions and 143 in private dwellings. On June 30th, 1904, 479 of them were segregated on Robben Island and 492 at Emjanyana, while six apparently were at the small station at Kokstad. The above figures for the colony do not include about 100 leprous persons from the Orange River Colony who are segregated at Robben Island. In the census report the matter is well summed up as follows: "There has been a decided increase in leprosy and it has not yet been adequately coped with for lack of asylum accommodation; many hundreds of the leprous die in their homes under no medical supervision or regulation. The medical officer of health of the colony estimated the number of lepers still at large in 1903 as at least 1000. Between 1893 and 1903, on an average 286 fresh cases have been discovered per annum without any very special endeavour to discover fresh cases, but only 190 per annum have been sent to asylums. There is no decided sign as yet of diminution of the number of occurring cases, notwithstanding the large numbers sent to the leper asylums." These are not very cheering figures for those who desire to see leprosy diminished to a vanishing point at no distant date; but when we learn from the report of the medical officer of health that the discovery of the leprous depends entirely on notification made by medical men and persons under whose observation they may chance to come, so that only well-marked cases are brought to light, the prospect seems still more remote. In the native territories especially, it is stated, "only some of the more obvious cases have been brought to notice."

Sufficient has now been said to show how from small beginnings the disease has spread over the country and become a most serious problem. The numbers in Cape Colony at present approach those existing in Norway in 1856 and it has taken half a century of segregation in a civilised and educated people to reduce that number to less different thing from producing the disease. I have seen various animals living for long periods in commensal relations with patients, such as dogs, cats, rats, mice, fowls, and birds of various kinds, but though carefully looked for no symptoms of the disease were noticed. One cat and two mice showed signs of nasal ulceration but microscopic examination showed no bacilli and in the case of one of the mice the condition was epitheliomatous, so that the other two instances were probably the result of trauma. The theory that the disease is conveyed through an intermediate host is certainly an enticing one but at present it lacks any supporting evidence whatever. Fleas, bugs, acari, and other skin parasites have been suggested as likely go-betweens but proof is still to seek. If, on the other hand, the nasal mucous membrane is the primary seat of infection, the intermediate host theory must go by the board. The means by which implantation can take place on the mucous membrane can be easily understood.

During the many years Robben Island has been occupied as an asylum only two cases of communication have, so far as I am aware, been recorded on good evidence, and I have not heard of any at Emjanyana. In this negative respect the South African asylums are very much at one with similar institutions in other parts of the world. Still, there are few such asylums where some recorded cases of communication do not exist. Where the association of individuals is that of daily social domestic intercourse the cases of communication recorded become enormously increased, as is the case in consumption.

My experience of the treatment of the disease has been much on a par with that of most others. The serum treatment, of course, had a good trial as we were liberally supplied with "anti-leprotic" serum from Bogota, prepared by Dr. Carrasquilla; also serum prepared by Dr. Herman from Dr. P. S Abraham's laboratory in London, while we made ourselves a considerable amount of serum from the blood of arrested cases of leprosy. We used control experiments with various animal sera, an account of which will be found in the Proceedings of the Leprosy Congress in Berlin, 1897. The results were quite negative. Indeed, it is difficult to see how a bacillus the toxicity of which is so slight can be inhibited by serum treatment. Extracts were made by us of enormous quantities of bacilli and these injected into rabbits produced no toxic symptoms whatever Treatment by anti-leprotic sera, therefore, may practically be considered out of court in this disease. The whole pathology is essentially different from that of the acute affections where antitoxic sera are of value.

It would take up too much time to describe my experiences of treatment by different drugs, but I may say at once that I experienced very much better results with chaulmoogra oil than with any other, and there is such a general consensus of confirmatory evidence from many quarters that there can be no doubt of the distinct value of some constituent of this substance in leprosy. I say some constituent, for the oil is a highly complex body and its pharmacology is as yet far from worked out and it is probable that as now supplied its composition is by no means uniform. An approximate analysis gives gynocardic acid 12 per cent., palmitic acid 64 per cent., hypogæic acid 4 per cent., and coccinic acid 3 per cent., in combination with glyceryl as fats, but the first two are present in the free state as well. Long ago it was noted by Dr. Young of Florence that in treating leprosy with this substance bronchial affections were markedly benefited and this was also my experience. No doubt the gynocardic acid has a good deal to do with this but some of the other constituents have a distinct and unmistakeable effect on the nutrition of the skin and the mucous membranes. Cases using the oil systematically never needed tracheotomy for the relief of laryngeal symptoms and a marked fall in pulmonary complications followed its general use; there was a greatly improved appearance of the cuticle generally and it undoubtedly promoted comfort or prolonged life. This was recognised by the more intelligent patients. The results were up to a certain point in my opinion striking. 120 minims three times a day after food can in time be easily borne for long periods, diluted with equal parts of olive oil, or the same quantity can be given in capsules. The changes can be rung by hypodermic injections. As much as ten cubic centimetres of the pure oil diluted with equal parts of olive oil injected into the loose areolar tissue of ree times a week without much inconvenience. It is rapidly absorbed and out of many hundreds of such injections I have not seen one followed by abscess or by unpleasant respiratory symptoms. Accompanying this treatment inunction of the oil, antiseptic lavage of the nasal cavities, and prolonged warm baths make unmistakeable amelioration in the patient's condition. Those who are interested in the subject I would refer to a short paper I wrote in the *South African Medical Record* in 1903, where they will find the whole question discussed in some detail. The results with a substance like chaulmoogra oil are such as to lead us reasonably to hope that a medicinal agent will one day be discovered which will act even more powerfully in leprosy and that its action will be reinforced by means which will raise the general opsonic powers of the blood serum. Indeed, the researches of Wright lead us confidently to anticipate that the latter means of attack on chronic bacterial disease may be definitely developed. Still there can be no doubt that the parasitism of the bacillus lepræ presents problems peculiarly its own. It is the benign character of this bacillus, its non-toxic properties, and the fact that, to some extent, at any rate, it can withstand the enzymic action of the white corpuscle which cause the whole chronicity of the process, an example of the law which has been well enunciated by Theobald Smith that the more parasitic a pathogenic organism becomes the less actively aggressive it is and the more it attempts to establish itself by purely defensive measures. It is the defences which surround it which cause the clinical symptoms of the disease in leprosy. Break these down and the solution of the problem will not be far off.

The utility of x ray treatment is more than doubtful and if any of the favourable results which have been recorded are at all dependent on the dermatitis caused, the outlook is not hopeful in this direction. Erysipelas causes an acute and severe dermatitis in the cases of leprosy which it attacks. I have seen many such cases after repeated erysipelatoid attacks which certainly caused temporary improvement relapse into their former condition. The weakened innervation of the skin in nodular leprosy makes the subject specially prone to the attack of the streptococcus erysipelatos and outbreaks can only be prevented by the most thorough attention to the sanitary condition of wards and buildings.

Till, therefore, we can obtain further light on the pathology and treatment of leprosy it must be combated chiefly by segregation and isolation, making the hardships unavoidable in such a procedure as tolerable as possible. When we remember that the great bulk of the patients in Cape Colony are of the coloured and native races it is evident that this isolation can hardly be arranged on the voluntary Norwegian system, and it must be recognised that in all the circumstances the Government of the colony is doing its best in the interests of the community and the patients to tackle a perplexing problem. It might be supposed that a great deal could be done to reduce the number of those segregated and thus to infuse the afflicted community with some comforting hope as to their future prospects by the discharge of cases when the disease had ceased to be infective. There can be no doubt whatever that this occurs in a large number of the maculo-anæsthetic cases The ulcers and deformities in the old-standing cases of this class are undoubtedly trophic and are caused by the defective innervation of the tissues. Though bacilli can be found in the nerves of very old-standing cases of this nature they are in all probability dead and in any case they are so anatomically entangled that no danger need be feared. The fact is that these cases have long passed the infective stage of nasal ulceration and, strictly speaking, can no longer be considered a source of communication. This, I think, must be freely granted and, indeed, in fairness insisted on. A very few of the nodular cases become arrested. But when we come to consider the discharge of such cases we meet the disappointing fact that a very large number are permanently incapacitated from earning a livelihood, and if not confined in an asylum as certified lepers would have to be supported by the State as chronic sick paupers. The experiment has been tried here on a small scale in a specially selected class of such arrested non infective cases and the results are not very encouraging. Promising cases have been sent back to our asylum with a renewal of their trophic ulcerations or deformities, so that they attracted attention and consequently could not obtain employment. Thus, there exists a very large number of cases who must certainly be defined as extending from the effective opportunity of communication till the first characteristic symptom of invasion appears but of this period in leprosy nothing is with certainty known. What is incorrectly spoken of as the *incubation period is the long period during which the disease* gives rise to no symptoms or appearances which excite suspicion in the minds of the patient or his friends. Significant prodromata are also in my experience very unusual in the vast majority of cases. On looking back the patient usually and pardonably *mistakes some* intercurrent indisposition for an initial symptom of invasion. The so-called leprotic fever is usually merely the lighting up of pre-existent leprous foci in the body by the dilatation of terminal vessels during the course of some intercurrent febrile attack.

Everything, indeed, tends to make it probable that the disease begins (how long after the implantation of the bacilli cannot at present with certainty be known) as a small collection of round cells under the mucosa of some part of the nasal cavity. Some of these round cells which are derived both from leucocytes and from the proliferation of connective tissue corpuscles, implanted bacilli, of course, being the starting point of the protective collection, contain bacilli which pursue some part, at any rate, of their life history in their interior. These bacilli-containing cells may *continue anchored at the* spot or may make their way into the capillary or lymphatic circulation. Their dissemination *to distant organs seems to be mainly by the blood stream,* and they do not with ease pass along the fine lymphatic channels. The comparatively slight implication of the lymphatic gland in this disease is an evidence of the latter statement. Those cells carried away by the blood stream come to anchor in situations where there is a tendency *to intermittent stasis* or slowing, physiological or anatomical, as the case may be, in the fine capillary circulation, and at such situations the process is repeated. *Organs or* systems where there is a rapid, free, and continuous current of blood are thus, as we might expect, practically immune from the leprotic granulomas; notably, accordingly, are the lungs, the brain, and the spinal cord free from attack; and just as we have in leuco*cythæmic conditions* an *infiltration* and enlargement of the liver and spleen, so we have such in leprosy by bacilli-containing leucocytes. The increase in size of these organs may be enormous; while the enlargement of lymphatic glands is slight or practically not noticeable. It is surprising, considering the enormous changes in the spleen *and liver in nodular leprosy,* that the condition of these organs has not attracted more general attention in the literature of the subject. Thin sections of the liver in early nodular leprosy afford the best material for studying the essential pathology of the disease. The whole process is one of obstruction by accumulating foci; the bacilli are not destroyed in the attacking cells, nor do they secrete a toxin sufficiently powerful to cause necrosis *of the enveloping protoplasm, so that localised accumula*tions of bacilli-containing cells take place which, by obstruction and pressure, cause all the symptoms; the process is naturally an exceedingly slow one and subject to periods of regression and quiescence and it is this benign character of the bacillus lepræ which paradoxically explains the chronic intractable nature of the disease and the dreaded deformities. Further research is necessary to elucidate the remarkable selective nature of the *lesions in maculo anæsthetic* leprosy, but it is certain that the neuritis is of pressure, not of toxic origin. Were the latter the case the axis-cylinder destruction in nodular leprosy with its enormous accumulation of bacilli *would be widespread. But the characteristic* absence of coagulative necrosis in itself proves the absence of toxin. In my own hands the injection of concentrated extracts of tissues containing packed infiltration of bacilli produced no appreciable effect on animals.

Though the implication of the nasal region in leprosy has long been known it is only recently that its bearing on the mode of communication of the disease has been suspected. In a nodular case of moderate severity the nasal mucous membrane can be seen studded with ulcerating patches of varying size; besides these, tiny whitish specks can be noticed under the membrane which on microscopic examination may be seen *to consist of minute collections* of round cells surrounding and containing masses of bacilli. It is not unusual to regard these as the earliest stage of the leprotic process and that it is from such a particular minute focus that the disease first begins its spread. The cicatrices of small ulcers which have healed can also be observed. One of the earliest signs of nodular leprosy is a slight erythema of the skin about the root of the nose and eyebrows, some*times extending* to the malar regions, and even with these slight signs extensive ulceration of the nasal mucous membrane may be found with abundant bacilli practically in almost a pure culture.

Questioning the more intelligent patients I have frequently found *that they had very early noticed* nasal obstruction as preceding the symptoms of disease which first caused them anxiety, though naturally they did not recognise the significance of this till it was pointed out to them. I examined the nasal secretion in more than 300 cases and in practically all the nodular and *mixed cases bacilli* were found more or less abundantly and in some of these they were in enormous quantities. Early cases also showed *bacilli from small nasal ulcers* when there was no ulceration on any other part of mucous membranes or on the skin. In nearly 10 per cent. of the early maculo-anæsthetic cases I found bacilli in the nasal secretion and this preponderance in the early maculo-anæsthetic cases seemed to me significant. *A few of the latter cases afterwards showed signs of* becoming mixed cases but this was decidedly in my experience an uncommon course. That bacilli seemed to be more commonly found in the nasal secretion of the earlier maculo-anæsthetic cases suggested a disappearance of nasal ulceration in the old-standing cases of *this type,* so that it would seem reasonable to infer that in such cases the nerve lesions are secondary to the nasal focus, and are originated from *bacilli* which have *migrated* from it through the medium of the vascular current. The original nasal focus had healed and disappeared, leaving the skin and nerve lesions as permanent effects but which are really of a secondary and pathologically subordinate *character. In a sense the original* nasal ulcer would correspond to the primary hard syphilitic sore, which disappears to be followed after a period by secondary symptoms. I offer this not as a case of pathological parallelism but as a suggestive analogy. Why the bacilli or the bacilli-carrying cells should select the very specialised sites they do in certain peripheral nerves needs further elucidation, but we may feel fairly confident that the reason is not physiological *but anatomical and that vascular* entanglement is its basis. In the mixed and nodular varieties the pathological process is a far more active one; there is a more vigorous general reaction of the tissues, as shown by the general leucocytosis and the condition of the liver and spleen. The leucocytosis, *however, defeats its own object* because it spreads the bacilli by means of bacilli-carrying cells in whose substance the bacilli retain their vitality. While clearly seeing the weak points in the above *explanation of the* two varieties of leprosy my experience of the disease leads me to regard it favourably.

Granting the above premisses, it is quite possible that in some individuals the nasal ulceration may be small and transitory and that no secondary lesions may occur or of very trifling nature. I have seen cases of an undoubtedly maculo-anæsthetic nature when there were only two or three small maculæ on *the body with a very slight* contraction of the fifth and fourth digits of one hand and the whole process stationary over some years. A lesser degree of involvement would escape notice, and some of the cases I refer to would certainly have done so but for the reason that they were convicts and therefore had been subjected to a rigid medical scrutiny. In some there were no bacilli in the nasal secretions—at least, none were found after a careful search. It is therefore quite possible that there may exist unrecognised cases where the disease consists practically of slight nasal ulceration alone. Yet such cases may at one period be sources of infection.

From what we know of the variation of virulence in pathogenic bacteria in some diseases it is also quite possible that the virulence of the bacillus lepræ may diminish in infective potency as time goes on while its power *of growth* in the body is retained. These cases may be most infective at the very earliest stage of nasal ulceration when the outward symptoms are least apparent, and certainly some of the *histories of patients* who were in contact with early slight cases lend some colour to this supposition. Certainly great difficulties surround the actual circumstances of the *communication of the disease* from individuals. The fact that it seems almost impossible to *inoculate* animals with the disease shows that there is some very special relation between seed and soil. *Of course,* I am aware that some local growth has been produced by implantation in *monkeys and other* animals but this is a very patient must thus be said to have died from an acute hæmorrhagic septicæmia without evidence of meningitis

It remains to discuss the evidence as to the nature of the coccus. Few Gram-negative cocci are known to be pathogenic for man; the only ones with which I am acquainted are micrococcus catarrhalis, the gonococcus, and the meningococcus. As regards the first two, I know of no recorded case in which they have been proved to cause an acute hæmorrhagic septicæmia such as is known to occur in certain cases of cerebro-spinal fever. The gonococcus could here also be excluded by the characters of the growth on culture media and micrococcus catarrhalis with almost equal certainty. With the help of Dr. M. H. Gordon I tested the organism as regards its metabolic powers on a series of some 18 carbohydrates, glucosides, and alcohols, adding to the culture media a little sterile raw ascitic fluid. An acid reaction was produced with glucose, levulose, galactose, maltose, and dextrin, while mannose, saccharose, lactose, glycerine, mannite, and the other substances tested remained alkaline. These reactions correspond in every detail with those of the meningococcus isolated from cases of *posterior basic meningitis*. The coccus further corresponded in every respect with that organism in its form, size, staining reactions, cultural characters, and pathogenic effects upon the guinea-pig. I therefore feel justified in asserting that it was the classical meningococcus—the diplococcus intracellularis meningitidis of Weichselbaum.

I have ventured to give the details of this case at length because I regard it as one of considerable importance. There is a large body of evidence to show that the infecting agent in epidemic cerebro-spinal fever is the meningococcus and it is known that in this disease hæmorrhages are common and that in severe and fulminant cases they may form the striking feature—that, in fact, there are acute septicæmic cases of the disease, fatal before the typical meningeal symptoms have had time to develop. It is equally well known that a common sporadic form of meningitis in children, not necessarily fatal and associated with a special localisation about the posterior fossa of the base of the brain, is to be traced to an organism indistinguishable from the meningococcus. Many have doubted that two diseases, so different in their *clinical course* and in their distribution, could be due to one and the same organism. Yet here is a case which can be paralleled only by the most fulminant type of epidemic cerebro-spinal fever occurring in a purely sporadic manner with no known connexion with any epidemic of the disease, which I have shown, as I trust, to be due to infection by a micro-organism in every respect identical with that of our ordinary posterior basic meningitis. Acute hæmorrhagic purpura may apparently depend upon a number of different infections and I know not how often the meningococcus may be included amongst them. I offer this case, by the courtesy of Dr. West, as one in which the record is fairly complete.

VOLVULUS OF THE CÆCUM TREATED BY REDUCTION AND APPENDICOSTOMY,

WITH REMARKS UPON THE OPERATION OF APPENDICOSTOMY.[1]

BY R. CHARLES B. MAUNSELL, M.B. DUB., F.R.C.S. IREL.,
MEMBER OF COUNCIL, ROYAL COLLEGE OF SURGEONS IN IRELAND, SURGEON TO MERCER'S HOSPITAL, DUBLIN.

THIS communication is of interest, first, because in it is recorded an example of a rare form of intestinal obstruction; and, secondly, because the line of treatment adopted is novel and gives an opportunity, for the first time in Ireland, of discussing a very simple operation which, in my opinion, has a very useful future.

The patient, a married woman, aged 77 years, with a large family, was admitted to Mercer's Hospital, Dublin, on Jan 12th last. She was a very brown skinned, wiry-looking old woman who stated that up to 6 30 P.M. on Jan. 11th she had practically never been ill but that she had always been subject to obstinate constipation. On that evening, whilst at tea with her family, she was suddenly seized with violent pain in the umbilical region and her abdomen became swollen and hard within a few minutes. On the next morning she was seen by Dr. H. Knapp, who administered an enema without result and advised her to go to hospital. This advice was not acted upon until the evening. When I saw her her temperature was normal, her pulse was 120, and she seemed weak after her journey to hospital but said that her pain was less. Examination of the abdomen revealed fulness below the umbilicus, rather more marked on the right side. The muscles were not very rigid but there was distinct tenderness over the distended area. Vaginal and rectal examination gave no further information. A turpentine enema was ordered but the result was again negative; however, as the pulse-rate was distinctly falling we decided to allow the patient to rest before deciding upon operation. On the next morning she felt rather better and the pulse-rate had fallen to 92. During the day it again rose to 108, so I decided to operate. At no time had there been any vomiting. When the abdomen was opened a tensely distended cæcum and ascending colon were seen filling the lower abdomen and pelvis. These were deflated and withdrawn, when it was found that the cæcum and portion of the ascending colon had made a complete turn from below upwards and from right to left. The lower portion of the ileum having been carried in front of the colon was tightly wound around the neck of the strangulated large intestine. The twist having been reduced it was found that the cæcum and colon had a well-formed mesentery, thus rendering volvulus a possible and likely accident. Having closed the incision which had been made for deflation I determined to fix and to drain the cæcum by performing the operation of appendicostomy. In this instance I had to ligate and to divide a portion of the meso-appendix, but took care to leave sufficient blood-supply to the portion near the cæcum. A stab wound was made at the outer border of the rectus and the appendix was drawn through and fixed by two sutures, its distal end was amputated, and its lumen was dilated with sinus forceps. A gum elastic catheter was then passed through it into the cæcum and fixed in position by an encircling ligature. The after-history of the case was uneventful except for some slight suppuration which occurred in the abdominal wound about eight days after operation, evidently due to infection of the incision when the intestine had been opened for deflation.

The after-history of the appendicostomy is of interest. The catheter was left in position for four days, when the bowels were well cleared out by castor oil. From the first a small quantity of fluid fæces and a large quantity of intestinal gas escaped through the catheter, thus keeping the intestines free from gaseous distension and rendering the patient's convalescence most satisfactory. As soon as the appendicostomy had completed its mission it became necessary, or at least advisable, to close the little opening. Up to the present operators who have performed appendicostomy have considered it necessary to open the abdomen and formally to excise the stump of appendix from the cæcum. It occurred to me that this was an unnecessarily severe sequel to such a trivial operation and that simple excision or invagination of the mucous lining of the stump of appendix should suffice as the muscular tube which would be left would soon cicatrise. I found that it was extremely easy to excise the mucous lining by means of a dissecting forceps and a tenotomy knife, the muscular tube healing soundly within a few days.

On March 20th last I again made use of the appendix in this manner in the treatment of a girl, aged 11 years, from whom I had to remove some four feet of small intestine for acute strangulation by an omental band. The chances of the little patient were practically hopeless from the start, but although the event was fatal yet the appendicostomy opening worked well and prevented abdominal distension

I have determined to give this operation a very thorough trial as a *preventive of* distension in emergency intestinal resections or in operations for diffuse or general peritonitis. Up to the present I have sometimes used Paul's glass tube in such, but now I am of opinion that we have found a simpler and equally effective method of preventing ileus. Beyond recording the facts as stated above I have little left to say, as the ground has been taken from under me by Mr. C. R. B. Keetley who has ably dealt with this subject in the *British Medical Journal* of Oct. 7th, 1905, and by Sir William H. Bennett in THE LANCET of Feb. 17th, 1906, p. 419. I may nevertheless mention the indications which these surgeons considered non-infective to whom it would be showing no kindness to discharge, and who if discharged would soon drift back again to the asylum by stress of circumstances or succumb to poverty or starvation. Even if such cases could count on their relatives for support the state of popular feeling is not favourable, and their charitable relatives would in many cases be involved in the social ostracism. A very few are not so incapacitated as to be unable again to take their place in the social environment they previously occupied, and every effort is being made to sift out and discharge under conditions which admit of their subsequent surveillance these hopeful cases.

[1] A paper read before the Surgical Section of the Royal Academy of Medicine in Ireland on March 23rd, 06

In the light of our present knowledge it is difficult to see what more can be done except to deal as generously as they deserve with those unfortunate people who, in the full possession of their faculties and for no moral offence, are isolated practically for life for the general good. It is certainly doing these people no kindness to suggest to them that they are being dealt with unjustly and ignorantly in the name of science. Such statements have recently been spread broadcast by a regular newspaper propaganda carried on—with the very best intentions no doubt—by Mr. Jonathan Hutchinson and have been the occasion of great discontent and unrest among the unfortunate sufferers and anxiety to the authorities. But in all the circumstances it certainly would seem that a more sustained and continuous effort should be made on behalf of those people in the way of experimental and scientific research in our well-organised asylums which are so suitable for a considered plan. It is almost useless to appoint men, however well qualified, with a roving commission, so to speak, to make discoveries in so wide a field as that of leprosy. The effort should be made in conjunction with a scientific organisation such as one of our flourishing schools of tropical medicine. In coöperation with the Government these schools might periodically send out to our asylums a research scholar or scholars who would under the direction of the scientific staff of the school have a definite objective mapped out for them to attain, if possible, during the period of the research. In the light of my experience some such plan—modifications will easily suggest themselves—is the only way in which we may expect systematised results of practical and scientific value, and I would humbly suggest its consideration to the distinguished medical scientists who are now here to afford us the helpful advice they are so competent to give; indeed, to be helpful in this way is, I take it, one of the principal objects of the British Association in its visits to different parts of the Empire. That the disease can be entirely eradicated no one can for a moment doubt; that inquiry into it and practical efforts for its suppression are not carried on with desirable vigour is certain. Its continued extension in a civilised community can be nowadays regarded in no other light than a stigma. Let us hope that this condition of things may ere long be altered and that by the end of the present century, so far as South Africa is concerned, leprosy may be reckoned among "the poor unhappy far-off days and things of long ago."

Cape Colony.

A CASE OF ACUTE MENINGOCOCCAL SEPTICÆMIA.

BY F. W. ANDREWES, M.D. OXON., F.R.C.P. LOND., D.P.H. CANTAB.,

PATHOLOGIST AND LECTURER ON PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL.

IT is well known that cerebro-spinal fever is often accompanied by cutaneous hæmorrhages. But it is a rare thing for meningococcal infection to be recognised as the cause of a fulminant purpura apart from outbreaks of cerebro-spinal fever. The following case is thus of unusual interest.

The victim was a medical man, 53 years of age, in practice in the City. He was in his usual good health on Feb. 10th and sat up all night with a patient under his care. There had been no contact, so far as is known, with any case of meningococcal infection and no case of cerebro-spinal fever is known to have occurred elsewhere at the time in the City of London. On the following day he seemed quite well; he ate his dinner as usual in the evening and smoked a cigar afterwards, conversing with his friends. It is said that he had a little shivering and malaise that night but on the morning of the 12th he felt ill and did not get up, though he did not think it worth while to send for a medical man. Towards midday he was worse and the appearance of spots on the face caused those who saw him to call in Mr. Alfred Chune Fletcher. Mr. Fletcher called in Dr. Samuel West in consultation and in the course of the afternoon the patient was removed to St. Bartholomew's Hospital under Dr. West's care, being placed in an isolation ward as it was not clear from what infection he was suffering. I am indebted to Dr. West for permission to publish the details of the case.

When I saw the patient about 5.20 P.M. he was in a moribund condition, with a profuse hæmorrhagic purpura from head to foot. The temperature was 99·4° F. and the respirations were 34 per minute; the pulse was not perceptible at the wrist. He was practically unconscious but could be roused to open the eyes which, indeed, he did but a few minutes before his death soon after 6 P.M. There were no evidently meningeal symptoms and death occurred suddenly at the end.

It was evident that the condition was one of a profound septicæmia and steps were taken to ascertain its nature. Dr. J. H. Thursfield prepared a syringe and withdrew blood from the basilic vein less than half an hour before death. At the same time I prepared films of the blood and carried out a leucocyte count. The case was so manifestly a hopeless one that all that could be expected was the melancholy satisfaction of establishing the diagnosis.

The results of the blood examination were as follows. The blood drawn from the finger, which was much cyanosed, was dark and viscid. It showed 12,800 leucocytes per cubic millimetre (the mean of two separate estimations by Dr. Thursfield and myself); 320 nucleated reds (normoblasts) were present per cubic millimetre. The differential count gave: lymphocytes, 23 per cent., 2944 per cubic millimetre; polynuclears, 68 per cent., 8704 per cubic millimetre; neutrophile myelocytes, 5 per cent., 640 per cubic millimetre; large mononuclears, 2·5 per cent., 320 per cubic millimetre; and eosinophiles, 1·5 per cent., 192 per cubic millimetre. There was thus a trivial polynuclear leucocytosis, with the myelocytes and normoblasts commonly seen in very grave infections. The most interesting feature of the films lay in the presence of large cocci, which were *exclusively intracellular*, being inclosed in pairs or groups of half a dozen, rarely more, in the polynuclear leucocytes. In one myelocyte some were seen. No single free coccus was seen in the blood. The idea that these were the meningococcus was not entertained till the result of the cultures was known but it is of interest to note in a septicæmia the same intracellular disposition of the cocci so familiar in the meningeal affection. The blood withdrawn from the basilic vein was distributed in broth tubes and over agar-agar. Some were incubated anaerobically but these yielded no growth. The aerobic ones yielded a pure and abundant growth of a large coccus, forming whitish semi-translucent colonies and negative to Gram's stain. Subcultures on gelatin at 20° C. yielded no growth at all but on nutrose ascitic agar, on ordinary agar, and in ascitic bouillon subcultures grew vigorously. Two guinea-pigs were inoculated on Feb. 13th with one of the original cultures from the blood, the one subcutaneously, the other intraperitoneally. No effect was produced by the subcutaneous inoculation; the animal remained in good health with scarcely any local reaction. The animal inoculated intraperitoneally was found dead in less than 24 hours; there was no very evident peritonitis but the coccus was recovered in pure culture not only from the peritoneum but abundantly from the heart's blood. The animal had died from an acute septicæmia unattended by any hæmorrhages.

At the post-mortem examination of the patient, performed the day after death by Dr. W. Langdon Brown, the appearances were as follows. In addition to profuse cutaneous hæmorrhages large hæmorrhagic patches were distributed along the mucosa of the intestine. Both suprarenals were in an intensely hæmorrhagic condition, dark purple in colour, swollen, and contrasting strongly with the kidneys, which were but slightly congested. The spleen was quite small and not in any way engorged or dark. There were extensive subarachnoid hæmorrhages, especially over the front and base of the frontal lobes of the brain, but there was no appearance of meningitis, nor on subsequent microscopic examination of the meninges could any evidence of actual meningitis be detected. The extravasated meningeal blood yielded, however, a more profuse growth of the coccus on culture than did blood withdrawn from the heart. The patient must thus be said to have died from an acute hæmorrhagic septicæmia without evidence of meningitis.

It remains to discuss the evidence as to the nature of the coccus. Few Gram-negative cocci are known to be pathogenic for man; the only ones with which I am acquainted are micrococcus catarrhalis, the gonococcus, and the meningococcus. As regards the first two, I know of no recorded case in which they have been proved to cause an acute hæmorrhagic septicæmia such as is known to occur in certain cases of cerebro-spinal fever. The gonococcus could here also be excluded by the characters of the growth on culture media and micrococcus catarrhalis with almost equal certainty. With the help of Dr. M. H. Gordon I tested the organism as regards its metabolic powers on a series of some 18 carbohydrates, glucosides, and alcohols, adding to the culture media a little sterile raw ascitic fluid. An acid reaction was produced with glucose, levulose, galactose, maltose, and dextrin, while mannose, saccharose, lactose, glycerine, mannite, and the other substances tested remained alkaline. These reactions correspond in every detail with those of the meningococcus isolated from cases of posterior basic meningitis. The coccus further corresponded in every respect with that organism in its form, size, staining reactions, cultural characters, and pathogenic effects upon the guinea-pig. I therefore feel justified in asserting that it was the classical meningococcus—the diplococcus intracellularis meningitidis of Weichselbaum.

I have ventured to give the details of this case at length because I regard it as one of considerable importance. There is a large body of evidence to show that the infecting agent in epidemic cerebro-spinal fever is the meningococcus and it is known that in this disease hæmorrhages are common and that in severe and fulminant cases they may form the striking feature—that, in fact, there are acute septicæmic cases of the disease, fatal before the typical meningeal symptoms have had time to develop. It is equally well known that a common sporadic form of meningitis in children, not necessarily fatal and associated with a special localisation about the posterior fossa of the base of the brain, is to be traced to an organism indistinguishable from the meningococcus. Many have doubted that two diseases, so different in their clinical course and in their distribution, could be due to one and the same organism. Yet here is a case which can be paralleled only by the most fulminant type of epidemic cerebro spinal fever occurring in a purely sporadic manner with no known connexion with any epidemic of the disease, which I have shown, as I trust, to be due to infection by a micro-organism in every respect identical with that of our ordinary posterior basic meningitis. Acute hæmorrhagic purpura may apparently depend upon a number of different infections and I know not how often the meningococcus may be included amongst them. I offer this case, by the courtesy of Dr. West, as one in which the record is fairly complete.

A CASE OF PICRIC ACID POISONING, FOLLOWED BY SEVERE CONSTITUTIONAL SYMPTOMS.

(Under the care of Mr. E. C. BEVERS.)

FOR the notes of the case we are indebted to Dr. E. J. Elliot, house physician.

A girl, aged 14 years, was admitted to the Radcliffe Infirmary, under the care of Mr. E. C. Bevers, on Sept. 27th, 1905, having been scalded by boiling water. On examination both elbows and a considerable area of the arms above and below were found to be burnt. There were also slight burns on the forehead, round the right ear, and at the back of the neck. The burns of the arms were partly of the second and partly of the third degree; that of the face was of the second degree. Extensive blebs had formed over all the areas. The blebs were pricked and the wounds were dressed every second day with a saturated solution of picric acid.

The patient progressed favourably until the morning of Oct. 4th, when she complained of not feeling well. Her tongue was furred, the lips were dry, and the expression was anxious. She was sick on several occasions during the day. Her temperature, previously normal, rose to 102·4°F. and the pulse from 88 to 154. The respirations were 24. The conjunctivæ showed a yellowish tinge, especially towards the outer and inner canthus of the eye, and the whole skin had a slightly icteric tint. A rash was found over most of the body. It was bright red in tint, papular, and non-hæmorrhagic. The papules were partly discrete and partly confluent, the whole having somewhat the appearance of a measles rash. It was distributed in the discrete form over part of the neck, the whole of the chest, the abdomen, and the back, the arms as far as the wrists, the front of the thighs, and a few patches over each ankle and over the toes. It was well marked and confluent over the sides of the chest, both buttocks, the back of the thighs, the calves, and the insides of the knees There was no rash on the face, the hands, or the front of the legs. The urine passed that morning was acid, with a specific gravity of 1022. It was clear and of a bright red colour, with a greenish shimmer on the surface. The blood was examined and a considerable diminution in the number of red blood cells was found, with some increase of the eosinophile leucocytes. The burns themselves were healing satisfactorily. The dressing was changed to spread boric ointment, as it was suspected that the patient's symptoms were due to the picric dressing. On Oct. 5th the temperature had fallen to 100·1° and the pulse to 130. The patient seemed better but the sickness still continued. The rash was more pronounced and more confluent. The conjunctivæ were a deeper yellow and the urine was of dark orange-brown colour with a large deposit of urates. On the 6th the temperature was 99·1° and the pulse was 96 The rash was beginning to fade. In parts there was evidence of slight hæmorrhages into the papules. The conjunctivæ were not so yellow. The urine was of the same colour. The rash continued to disappear gradually from this date, being invisible by the 12th.

The patient progressed favourably till Oct. 14th, when she was again seized with vomiting and looked ill. She complained of pain in the abdomen which was tender on palpation. The temperature remained normal. The bowels were opened with an enema. There was no blood in the stools or in the vomit. The pain was very severe and one-sixth of a grain of morphine hypodermically was needed to obtain relief She improved in a day or two and was discharged on Oct 24th. About four days before leaving the hospital she developed a small petechial rash on the lower part of the legs. The patient remained quite well at home for a week, but on Nov. 1st she felt the pain again in the "stomach" and was sick three times. No blood was noticed in the vomit. On Nov. 3rd she was re-admitted to the Radcliffe Infirmary under Dr. W. Collier. She was obviously extremely ill. There was severe abdominal pain which needed morphine to allay it. During the next three days she showed no improvement. She vomited blood, passed blood in the stools, and the urine was smoky and gave the blood reaction with guaiacum. Only a few petechiæ appeared on the forearms. On Nov. 7th she was a little better and subsequently made a rapid improvement and went home again on the 29th quite well, with the exception of a cloud of albumin in the urine.

Remarks by DR. ELLIOT.—Owing to the extensive use of picric acid as a dressing for burns and to the small number of cases published in which toxic symptoms have been observed it has occurred to me that this case is of sufficient interest to be placed on record. The general aspect of the patient, the vomiting, temperature, rapid pulse, and rash all pointed to some profound constitutional disturbance and it will be noticed that these symptoms only supervened after applying the picric dressing for seven days and ceased on the dressing being discontinued.

The points of interest with regard to the rash were: 1. Its resemblance in many respect to a measles rash; it was absent, however, from the face and behind the ears. 2. It was extremely well marked and confluent in those parts of the body in contact with each other and also where subjected to pressure.

The urine was examined by Dr. W. Ramsden, of the Oxford Physiological Department, whose report was as follows:—"The first sample of ——'s urine (Oct. 4th) was rich with some abnormal pigment. Subsequent samples were abnormal *only in the quantity* of the normal constituents. The abnormal pigment was carried down with the earthy phosphates precipitated by heat, the precipitate having a rich brown colour. It seemed probable, therefore, that it would turn out to be hæmatoporphyrin. I carefully followed Garrod's instructions for the detection of hæmatoporphyrin in the urine. The result was entirely negative. I have also tested carefully for methæmoglobin and hæmatin and find neither of these substances. Blood pigments and their simple derivatives are therefore absent. What the abnormal pigment is I am unable to determine. The existence of various urinary pigments about which nothing else is known is beyond question. Presumably it is one of these and its identification would require an elaborate research and a much larger quantity of urine than I possess." The examination of the blood and urine, combined with the icteric tint of the skin and conjunctivæ of the patient, would seem to point to a toxic condition in which destruction of blood corpuscles had taken place.

In previous cases which I have been able to find recorded in the medical journals very similar symptoms have been observed—viz., severe constitutional disturbance, rapid pulse, rise of temperature, rash, and yellow tint of conjunctiva and skin. One case showed vomiting and diarrhœa. Another showed all the above symptoms except the rash. In all cases the urine has been described as of a dark red, dark green, or port-wine colour, and in all the symptoms have abated on discontinuation of the dressing. From the occurrence of such symptoms as the above there seems to be reason for believing that the use of the saturated solution of picric acid as a dressing for burns is not without its dangers.

BEDFORD COUNTY HOSPITAL.

A CASE OF MOVEABLE LIVER AND VENTRAL HERNIA; HEPATOPEXY AND PLASTIC OPERATION ON THE ABDOMINAL WALL.

(Under the care of Mr. W. GIFFORD NASH.)

A WOMAN, aged 43 years, was admitted to hospital on May 30th, 1903, complaining of abdominal pain, discomfort, and weakness which made her life miserable. She had had eight children and her abdominal wall had bulged since her fifth confinement 11 years previously to admission.

On examination the patient was a thin woman, looking at least ten years older than her age. The uterus prolapsed when she stood up. The liver was displaced downwards, so that its lower edge was on a level with the umbilicus; it was freely moveable and could be pushed up into its normal position. The right kidney was freely moveable.

enumerate and bring this communication to a close with my own appreciation of this attempt to turn the appendix from its evil ways and to make it a useful member of the community of abdominal viscera. Mr. Keetley has collected all the records of this operation, from R. F. Weir's pioneer case down to the date of his communication, and suggests the following as indications: 1. Mucous colitis. 2. Dysentery. 3. Chronic ulceration of the colon. 4. Chronic constipation. In these conditions the opening is used for lavage and medication. 5. To fix and to drain an ileo-cæcal intussusception. 6. To drain and to prevent distension subsequent to operations for intestinal obstruction or when intestinal resection has been performed. In these instances it is used as a prophylactic measure. Sir William Bennett enlarges this list by including the following suggestions: (1) as a method of applying local treatment in complicated enteric fever, as suggested by Dr. W. Ewart; (2) as an improvement upon rectal feeding; and (3) as a substitute for gastrostomy or jejunostomy in very weak and emaciated patients.

I most heartily concur with all these suggestions and have here recorded the further indication of fixation of a volvulus of the cæcum and suggest that it should also receive an exhaustive trial as an aid in the treatment of diffuse or general peritonitis, arising from any cause, when a paretic condition of the intestines is present.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THREE CASES ILLUSTRATING OBSTRUCTION OF THE SUBMAXILLARY DUCT.

BY O. EICHHOLZ, M.D. OXON.

I HAVE within the last eight years observed three cases of affection of the submaxillary gland or duct of a mild character and the simplicity of the treatment is the chief feature that warrants publication. They were all different varieties, moreover. I do not know how frequently such cases occur in the practice of other medical men and a perusal of English and foreign text-books throws no light on this point. Two of my cases concerned the salivary duct of Wharton and in the third case this duct was apparently unaffected.

In the first case the symptoms came on suddenly and I am able to give the symptoms with absolute certainty and precision. There was a feeling of irritation in the floor of the mouth on the side affected and a feeling of tension along the line of Wharton's duct supervened with remarkable suddenness. The swelling of the gland was slight. On examination a few minutes afterwards the orifice of the duct was seen to be blocked by a pale yellowish mass about one millimetre in diameter. There was no difficulty in expressing it and on examination it proved to be of the consistence of putty and malodorous. The same symptoms occurred about a year afterwards and the same treatment was adopted. No recurrence has taken place since (eight years ago).

In the second case the patient found a swelling appearing suddenly in the position of the submaxillary gland externally one evening in December, 1904. I saw him on the following evening, the swelling being still present. It was distinctly tender and was said to become larger while eating. On questioning him he admitted feeling some discomfort under the tongue, as if there were a hair irritating the mouth. There was no difficulty in seeing that a hair was protruding from the papilla of Wharton's duct and it was readily extracted by the fingers, with the aid of a pocket handkerchief to obtain a firmer hold. The hair was about three-quarters of an inch long and the portion embedded in the duct was seen to be encrusted with hard mineral matter. In this case, there was therefore a salivary calculus which had formed round a hair of the moustache which had penetrated the orifice of Wharton's duct and passed along it to the extent of about half an inch. I advised the patient to avoid biting his moustache and no further recurrence has taken place up to the present.

In my third case the only symptom was swelling and some tenderness of the submaxillary gland in a boy, aged 14 years. The sudden appearance of the swelling pointed to some blocking of the duct of the gland but examination of the floor of the mouth did not reveal its nature and I therefore came to the conclusion that the obstruction was situated in the substance of the gland. The treatment adopted was to paint the skin with glycerine of belladonna and apply a fomentation. The swelling and discomfort disappeared by adopting these measures as quickly as they had appeared, the whole episode occupying under three days, and no recurrence has taken place. It is nearly two years since the above occurred.

There must be some doubt as to the precise cause of the swelling in this case as no plug or calculus appeared. It is possible that the obstruction may have been extruded spontaneously; according to Bergmann[1] a stone may suddenly make its appearance in the mouth, as during a meal, without having manifested its presence before, but such an event is said to be exceptional, whereas according to Da Costa[2] small concretions are often passed. It is of course possible that the blockage was the result of inflammation. The diagnosis of such cases as I have here recorded ought to present no difficulty. The sudden swelling of the salivary gland with the possible occurrence of a stone, foreign body, or plug of inspissated mucus or caseous-looking material in the duct are quite characteristic, while the almost immediate subsidence of the tumour when the obstruction is removed (as in my two earlier cases) allays the not inconsiderable alarm which these trivial affections cause the patient to feel.

Russell-road, W.

A CASE OF COMPLETE "SPONTANEOUS INVERSION" OF THE UTERUS.

BY G. S. MCKAY, M.B. ABERD.

ON Jan. 29th, 1906, I was called to a primipara the first two stages of whose labour were normal, but about 15 minutes after the birth of the child the patient with a strain expelled the placenta adhering to what appeared at first sight to be a tumour. A sulcus demarcated the point of attachment of the placenta to this mass. No fundus uteri could be felt in the abdomen but the hollow in its place was quite palpable. Having the following data—namely, (1) a distinct hollow in the abdomen in the place of the fundus uteri; and (2) a mass outside the vagina—I came to the conclusion that the case must be one of inverted uterus. The hæmorrhage being now very profuse I seized the neck of the inverted uterus, which lay outside the vagina, and by gentle pressure between the thumb and forefinger of the left hand the bleeding was controlled until I detached the adherent placenta with the right hand. The uterus was reinverted by pressure and counter-pressure between the two hands and slipped into its proper position not unlike the reinversion of a collapsed indiarubber ball. As the interior of the uterus might have undergone septic contamination from extraneous sources I washed it out with antiseptic lotion. The uterus soon contracted to the size of a cricket ball, firm and hard. The patient complained of little beyond a peculiar faintness until two hours after the reinversion, when she became very pallid and lost consciousness. She remained unconscious for a short time and had two such attacks during the day. After careful watching and guarding of the uterus, injections of salt solution, hypodermic injections of strychnine and ergot, and general treatment for hæmorrhage, the pulse, which was at first rapid and thready, gradually improved. During the next nine days the patient's temperature never exceeded 99·2° F. She made a good but slow recovery and is now quite well. She does not complain of any dragging abdominal pain and feels quite comfortable.

Wetherby.

[1] System of Practical Surgery.
[2] Modern Surgery.

mediastinal glands, four cases; primary sarcoma or cancer of the mediastinal glands or thymus, six cases; primary cancer of the lungs, six cases; and sarcoma of the pleura, one case. The complications included pleuritic effusion in six cases, in two of which it was hæmorrhagic; and invasion of the vertebral canal by growth in six cases causing paraplegia of sudden onset in four and of gradual onset in two cases. The secondary changes in the lungs were illustrated by drawings; the earlier symptoms in these cases were pain and cough, and the later—cancer of the lung (three cases)—sanguineous expectoration. Physical signs of intrathoracic pressure were present in 13 cases. The remaining physical signs and the duration of life were discussed and a short account of the individual cases was given.

Mr. A. Betts Taplin in his report on Treatment by Hypnotic Suggestion said that hypnotism had been evolved in the past from such a labyrinth of superstition and nonsense that he almost felt inclined to apologise for introducing the subject to the notice of a professional audience as an acknowledged branch of therapeutics. Its history during the last 170 years was full of absorbing, even of tragic, interest here and there, and was ably told in the works of many medical men, both in England and on the continent. Hypnotism was generally acknowledged by all observers to be a physiological and not a pathological condition, and to be absolutely free from danger in competent hands. It had been found most useful in those many cases which were the despair of the profession and which were characterised by pain, spasm, or other nervous phenomena, in which no organic cause could be found and for which no other therapeutic measures seemed to be of any avail. The time for its study and reception by the medical profession was ripe and to prevent its possible abuse in ignorant or unscrupulous hands it was much to be desired that as soon as possible its use should be limited by legal enactment to properly qualified persons under proper control.—Dr. Grossmann thought that no advance had been made in our knowledge of the subject for 20 years. The account he had given before the Medical Institution 18 years ago was based on a visit to Professor Charcot at the Salpêtrière and a stay at Nancy where he studied the methods and saw the patients of Dr. Liébault and Professor Bernheim. Professor Charcot's patients were all hysterical, while at Nancy every sort of patient was treated. Three phases were distinguished—lethargy, catalepsy, and somnambulism. The Nancy school recognised nine different degrees of susceptibility ending with somnambulism followed by amnesia. All the phenomena were explained by suggestion and the modes of producing the various stages of hypnosis employed by the Paris school were recognised as suggestions. The Nancy school considered the hypnotic state as analogous to sleep with the difference that the subject was *en rapport* with the operator, hearing and understanding him. Dr. Grossmann had no difficulty in hypnotising subjects, but he had never seen any therapeutic results in his cases—paralyses of ocular muscles, restricted fields of vision, &c.—nor had he himself seen the extraordinary trophic phenomena, blisters and burns, so graphically described by Professor Krafft-Ebing. It was always a difficult matter to find out how far the subject was really under the influence of the operator and to what extent he was shamming. For his own part he thought Braid's motto, "Unlimited scepticism is equally the child of imbecility as implicit credulity," was all very well but the following one was safer: "When you see a fact, doubt it."—Mr. A. E. Davis agreed that subjects often deceived the hypnotiser but could not accept the statement made by one of the speakers that hypnosis was produced in hysterical neurotic soil which, in his experience, was the least fruitful of all; he agreed with the theory of the late F. W Myers that the phenomena were produced in the subliminal consciousness, which was supported by the fact that the acuity of the senses could be enormously increased. He pointed out that of the 13 patients mentioned by Mr. Taplin two only were males. The objection of males to try hypnotism was a great drawback to its practice and study. Though he believed it was not possible to instil viciousness into a subject who had no natural inclination to it the dangers of being *en rapport* with some women subjects were obvious. He had repeatedly produced trophic changes. Convulsions in hysterical subjects could be obviated by self-confidence and knowledge on the part of the hypnotiser.—Dr. S. M. Whitaker said that a better description of the treatment would be "treatment by suggestion with or without hypnosis," for it was usually unnecessary to hypnotise the patient more deeply than the lightest lethargic stage when he would accept suggestions and the operator could obtain good therapeutic results. During treatment there should be no distracting sounds and sights. He used the method of "monotony." The cases suitable for this treatment were those in which there was functional disturbance, including most cases of organic lesion, and so far as this element existed it was possible to benefit the patient. He had obtained excellent results in the attacks of palpitation of exophthalmic goitre, headache, insomnia, and pain generally. Owing to the depth of hypnosis required for general anæsthesia the method was not likely to compete with ordinary anæsthetics.—Mr. O. T. Street said probably all were agreed that there was such a thing as hypnotism but were divided as to its usefulness. He asked, "Was not treatment by suggestion without hypnotism preferable?" Those who worked among the insane knew what beneficial results could be produced by suggestion, how the melancholic was encouraged to look on the brighter side of things, how the maniac was calmed by suggestion and example, and how it could be suggested to the hysterical that she could exercise self-control if she tried. The result from this form of treatment might be slow but it was certainly more sure and lasting than that produced by hypnotism.—Dr. T. R. Glynn, Dr. Stanley A. Gill, and Dr. W. B. Warrington also took part in the discussion.

FORFARSHIRE MEDICAL ASSOCIATION.—The last ordinary meeting of this society for the present session was held in Dundee on April 6th, Dr. R. Sinclair, the President, being in the chair.—Mr. D. M. Greig showed a man, aged 68 years, after operation by Evagination of the Testicle for Large Double Hydrocele, with a stereoscopic photograph of the condition before operation. He emphasised the simplicity and safety of the operation and expressed surprise that the certainty of a radical cure had not led to a more general appreciation of its merits.—Mr. Greig also showed an infant who had at birth an Occipital Meningocele larger than its head. The cyst collapsed at birth but soon refilled and at the age of five and a half weeks Mr. Greig successfully removed the tumour. A stereoscopic photograph of the condition at the time of operation was exhibited and the actual tumour was demonstrated.—A third case shown by Mr. Greig was one of Morphœa of the Right Forearm associated with contraction and atrophy of the muscles in the upper half of the limb attached to the external condyle of the humerus. The patient was a woman aged 80 years and had a history of only slight injury. The hand was in good condition, though no pulsation could be felt in any of the vessels at the wrist, and the affection seemed to implicate the musculo-cutaneous nerve in its distribution to the skin and the musculo-spiral nerve in its distribution to the muscles and the radial as regards sensation. Mr. Greig expressed the opinion that the condition was primarily a nerve affection and pointed out the incongruity of the distribution with a vascular derangement.—Professor J. A. O. Kynoch showed a specimen of Carcinoma of the Uterus removed by vaginal hysterectomy from an unmarried woman, aged 56 years. The disease, which had been confirmed by microscopical examination, was confined to the endometrium. In contrast to this was a specimen of carcinoma in which the whole body of the uterus was involved except a small part at the fundus. A third uterus which showed a condition of diffuse adenoma of the endometrium with a suspicious character on microscopic examination had also been removed by vaginal hysterectomy. He also showed an ovarian cyst with torsion of the pedicle which had produced symptoms calling for immediate operation in a young multipara 14 days after a normal confinement. A fibroid removed from the anterior wall of the uterus after a previous operation by removal of the appendages which had no effect in checking the excessive hæmorrhage, the most prominent symptom, was also shown. The second operation was successful in giving relief.—Professor D. MacEwan read a paper on the Local Treatment of Surgical Tuberculosis. In introduction he emphasised the importance of constitutional as an adjunct to local treatment and pointed out the desirability of extending the modern sanatorium method to the hospital class of cases and stated that the natural tendency to cure of tuberculosis in bone and joints was probably greater than in pulmonary tuberculosis. In many cases he considered that it was advisable to combine the open-air treatment with complete bodily rest in the

When lying down the abdominal wall was extremely flaccid and the recti muscles were widely separated; but when the patient raised herself the intestines bulged forwards between the recti, causing a large ventral hernia measuring nine inches vertically by four laterally. There was present a marked condition of enteroptosis. To remedy this condition suture of the liver and repair of the ventral wall were decided upon.

Operation was performed on June 15th. An incision was made in the middle line about nine inches in length, commencing six inches above the umbilicus. The liver was pushed up and kept in place by four buried celluloid thread sutures, small button-hole skin incisions being made for this purpose over the sites of the sutures. The edge of the liver was thinned out and more fibrous and tougher than usual. The ventral bulging was dealt with by excising a large elliptical piece of skin and peritoneum. The wound was closed by suturing in three layers the peritoneum, the rectus sheath and muscle, and the skin.

The patient made an excellent recovery and when seen at the end of 1905 the liver remained fixed in its normal position and the median incision was quite firm. She had immensely improved in condition and health and looked years younger than before operation.

Remarks by MR. GIFFORD NASH.—In THE LANCET of April 7th, 1906, p. 949, Mr. W. Watson Cheyne related two cases of hepatopexy and remarked on the small number of cases of operation recorded in medical literature. Dr. H. D. Rolleston also, in his work on "Diseases of the Liver," p. 35, mentions that Terrier and Auvray collected 15 cases of hepatopexy with 11 cures. Quincke, in the article on Diseases of the Liver in "Nothnagel's Practice," p. 398, suggests excising a wedge-shaped piece of the abdominal wall in the region of the linea alba.

The case I have related above was evidently an example of rotation of the liver on its transverse axis, so that the upper surface was in contact with the anterior abdominal wall. It was part of a general enteroptosis due to loss of muscular tone and stretching of the abdominal wall. The comparatively simple operation produced the most beneficial results.

Medical Societies.

LIVERPOOL MEDICAL INSTITUTION.

Sarcoma of Left Iliac Region.—Early Human Embryos.—Aneurysm of Ascending Aorta.—Villous Tumour.—Spinal Conditions leading to Acute Paraplegia.

A PATHOLOGICAL meeting of this society was held on April 5th, Mr. F. T. PAUL, the President, being in the chair.

After the exhibition of a large number of card specimens the PRESIDENT showed a patient with a Sarcoma of the Left Iliac Region which had remained stationary for 12 months; a piece had been removed for microscopical examination.

Dr. K. A. GROSSMANN showed Four Early Human Embryos collected for the purpose of embryological examination of the development of the eye. They were of about six, seven, eight, and nine weeks respectively and were all complete in amnion and with one exception in chorion also.

Dr. JOHN HAY showed a specimen of Aneurysm of the Ascending Arch of the Aorta which had ruptured at its posterior portion into the superior vena cava. The rupture caused sudden loss of consciousness and intense cyanosis with distension of the veins of the head and neck, shoulders, arms, and the upper half of the trunk. The patient recovered consciousness shortly after admission to hospital but died in 60 hours.

The PRESIDENT read a note on three cases of Papillomatous Growth, one of widespread villous tumour of the urinary organs, one of villous tumour of the rectum, and one of a large rapidly growing papilloma of the tongue believed to be malignant but ultimately proved to be innocent. Villous tumour of the bladder he believed to be primarily innocent with a marked tendency to become malignant; only favourable cases were permanently cured, some became cancerous, and others seeded themselves over the adjacent mucous membranes. Villous tumour of the rectum was almost invariably carcinoma from the first but being more accessible and less malignant than cancer of the bladder was frequently permanently cured by operation. Papilloma of the tongue was perhaps always innocent primarily but had an inveterate tendency towards malignant change in course of time. In discussing the value of reports by expert pathologists on the nature of new growths, he said that in difficult cases it was frequently impossible to decide, as was constantly done, on microscopical appearances alone; such reports were frequently wrong. It was necessary to consider the clinical and pathological evidence together and he strongly supported the suggestion recently made by Mr. A. W. Mayo Robson that in important cases the pathologist and surgeon should meet in consultation.

Dr. W. B. WARRINGTON gave a short sketch of the Pathological Conditions in the Spinal Cord leading to Acute Paraplegia. This might be due to a primary vascular disturbance, hæmorrhage, thrombosis, embolism, or the cause might be a primary inflammation. Primary hæmorrhage was rare and usually traumatic; it was considered (*a*) as epidural; (*b*) subdural, clinically negligible; (*c*) into the substance of the cord; and (*d*) into a pre-existing cavity—syringal hæmorrhage. A primary thrombosis was considered to be the cause of the usually named "transverse myelitis", and in this condition syphilitic arteritis was the common lesion. Many other forms of local destruction of the cord were also considered to be due to a primary ischæmia; these were tuberculous and syphilitic meningitis, compression of the cord, and the effect of tumours. Dr. Warrington discussed the pathological appearances presented by acute diseases of the spinal cord, the effects of acute degeneration, softening, hæmorrhagic infarction, coagulation, necrosis, and inflammatory œdema. He alluded to caisson disease as perhaps an example of pure ischæmia from gas embolism. Primary inflammation was, he thought, rare and probably included the disseminated lesions characterised by demonstrably infective causation. A remarkable example of such acute disseminated hæmorrhagic myelitis was mentioned and specimens illustrating its pathology were shown. Dr. F. E. Batten's view of the thrombotic nature of encephalitis and infantile palsy was noted and the relationship of Landry's paralysis to the other acute paraplegias was briefly considered.

Scabies.—Intratracheal Injection of Izal in Pulmonary Tuberculosis.—Intrathoracic Tumours.—Treatment by Hypnotic Suggestion.

A meeting of this society was held on April 19th, Mr. F. T. PAUL, the President, being in the chair.

Dr. F. H. BARENDT read a note on Scabies, emphasising certain points in diagnosis, mode of infection, and treatment. In cases where the primary eruption was incapable of detection—cuniculi not being recognisable—but the sites of the secondary eruption due to the pruritus were well defined, the patient should be treated for scabies. The nipple area in woman and the genital region in man should always be carefully examined, especially where the eruption between the fingers, in the case of cleanly individuals, was absent. Dr. Barendt drew attention to the method of distribution, which thus accounted for the universality of the lesions in long-standing scabies. He considered that infection was almost always nocturnal and the result of prolonged contact with an infected person and that the handling of bed- or body-clothes or shaking hands with a scabetic could communicate scabies was, to say the least, not proven. In ascertaining the source of infection it was necessary to question the patient upon his surroundings of the three weeks previous to the onset of itching. Dr. Barendt used the β-naphthol ointment first introduced by Kaposi. It was a superfatted soft soap containing about 9 per cent. of β-naphthol. It had the advantage of neither staining nor possessing a disagreeable odour and, above all, did not aggravate the secondary lesions, which sulphur ointment, especially in long-standing scabies, was liable to do.—Dr. G. G. STOPFORD TAYLOR stated that treatment was unsatisfactory unless all underclothes and bed-linen were boiled and those clothes which could not be so treated were stoved. The Liverpool sanitary authorities would undertake the stoving free of charge.

Mr. COLIN CAMPBELL showed a patient after 12 weeks' treatment by Intratracheal Injections of Izal in Pulmonary Tuberculosis.

Dr. T. R. GLYNN classified 21 cases of Intrathoracic Tumour under the following heads: Hodgkin's disease with implication of the mediastinal glands, four cases; sarcoma of some groups of superficial glands, with implication of the a patient, aged 37 years, suffering from paroxysmal attacks of abdominal pain. The attacks began with a sensation of dragging followed by acute pain in the right side. The patient suffered from constipation which was most pronounced during the attacks. Leucorrhœa was succeeded by xanthorrhœa. Menstruation was regular, the amount being moderate without any special symptoms. At the operation the uterus was found to be myomatous, the right ovary was occupied by a large adherent cyst, the left oviduct was inflamed, and there were firm adhesions between the tumours and the bowel. The uterus and the cyst with the left appendages were removed. On opening the cyst the contents were found to be suppurating and the wall contained solid adenomatous growth with malignant degeneration. The patient progressed satisfactorily without any evidence of recurrence. 2. Myoma of the Cervix from a patient, aged 32 years, suffering from menorrhagia but without any disturbance of the bladder or bowel. 3. Myoma removed from a patient, aged 36 years, by an abdominal intra-uterine myomectomy. The patient made a good recovery.—Dr. Frederick Edge showed: (1) Myoma of the Uterus which became strangulated and simulated cancer of the fundus, removed from a patient, aged 58 years, who was single and passed the menopause eight years previously. There was a family history of cancer. The patient had some pelvic pain during last winter. One month previously after walking sudden acute pelvic pain came on with a pulse of 160 and a temperature of 104° F. On examination a tumour was found closely adhering to the fundus, causing acute pain on manipulation. The diagnosis lay between an ovarian cyst with axial rotation, carcinoma, or a myoma undergoing malignant degeneration. At the operation the uterus was found to be retroverted with a strangulated myoma behind the right broad ligament. 2. A Pregnant Uterus of four months with an almost sessile myoma removed by supravaginal hysterectomy from a patient, aged 45 years, complaining of severe abdominal pain. At the operation the myoma was found to be intimately adherent to the uterus and bowel. The tumour was ligatured off with No. 5 silk but this cut through the tissue, causing hæmorrhage which necessitated removal of the uterus as well. 3. A Myomatous Uterus with Expanded Cervix removed by abdominal hysterectomy. The cervix was removed after supravaginal hysterectomy, leaving a portion of the anterior wall.—Dr. Edge read a short communication on the Advantage of Panhysterectomy over Supravaginal Hysterectomy, basing it on two fatal cases where the latter operation had been performed, the cause of death in one case being secondary hæmorrhage and in the other acute general peritonitis on the tenth day. The method of operation advocated was similar to Doyen's, with the addition of making peritoneal flaps anteriorly and posteriorly.—Dr. Smallwood Savage (for Professor J. W. Taylor) showed a large Uterine Myoma removed from a patient suffering from diabetes, aged 46 years. The patient had one child nine years previously and one miscarriage eight years ago. She complained of menorrhagia and bad diabetes for more than a year. The abdomen had rapidly increased in size for several months. The urine was acid and contained some albumin and much sugar. The progress had been satisfactory so far.—Dr. H. Macnaughton-Jones showed an Adeno-Carcinoma of the Left Ovary removed from a patient, aged 56 years, who complained of severe pain since a fall in December, 1905. On operation two ovarian tumours were found and a quantity of ascitic fluid escaped. In the wall of the left tumour malignant spheroidal cells were found.—The President showed a Spindle-celled Sarcoma of the Left Ovary removed from a patient, aged 50 years, who was admitted for an abdominal tumour and stabbing pain. The climacteric occurred six months previously. The pain increased during the last month and the abdominal swelling became more prominent. At the operation a large quantity of dark fluid escaped from the abdomen; the left ovary was occupied by a solid tumour which had rotated on its pedicle at least twice. This tumour was removed and no secondary deposits were found. The right ovary was fibrous but was not removed. The patient made a rapid recovery. The pathological report stated that the stroma showed all the characters of a spindle-cell sarcoma with areas of necrosis and hæmorrhage.

CORK MEDICAL AND SURGICAL SOCIETY.—A meeting of this society was held on March 28th, Dr. Richard P. Crosbie, the President, being in the chair.—Dr. Patrick T. O'Sullivan read notes of two cases, one of the Swallowing of Three-fifths of a Grain of Strychnine and one of Poisoning by Phosphorus. In the first case the patient was a man, aged 62 years, who had suffered from diabetic glycosuria for four years. A mixture consisting of two drachms of liquor strychninæ (B.P.) in four ounces of water was prescribed for him and he was directed to take one teaspoonful in a wineglassful of water after meals. He, however, whilst writing letters after dinner, poured out a wineglassful of the mixture and drank it off. An hour later, becoming alarmed, he sent for Dr. O'Sullivan who found him in a state of great excitement but showing no symptom of poisoning except some slight trembling of the leg muscles. He was watched for an hour and seen frequently during the evening, but no other signs appeared and next morning he was all right. He had swallowed three-fifths of a grain of strychnine and there were instances where a quarter of a grain had proved fatal. The explanations suggested by Dr. O'Sullivan were (1) that the strychnine was bad; (2) that the full meal prevented the rapid absorption of the drug; and (3) that owing to the advanced diabetic condition the drug was tolerated in larger doses than in the normal subject. In the case of phosphorus poisoning the patient was a child who had swallowed the heads of several lucifer matches. There was jaundice with enlargement and tenderness of the liver. The stools were clayey and smelt of phosphorus and in the dark showed faint phosphorescence. The urine was scanty and bile-stained and showed a small trace of albumin, but no leucin or tyrosin. The patient was restless and did not sleep at first, but afterwards became stupid and difficult to arouse. There was no trace of bile in the stools for 29 days. The child made a good recovery, being carefully nursed and treated expectantly.—Dr. N. H. Hobart read notes of a case of Fibromatous Tumour of the Capsule of the Kidney. The patient was a married woman, aged 26 years, and a primipara. Three days after a normal labour which terminated on Feb. 4th, 1906, a tumour of about the size of a small orange was noticed on the right side of the abdomen, at the level of the navel. On Feb. 28th Dr. Hobart saw the patient for the first time and found a large oval smooth tumour extending from the right iliac fossa to about two inches above the umbilicus. On March 4th, as the patient's temperature had been about 102° F. for some days, he aspirated and withdrew a small quantity of dark serum. On the 5th he removed the tumour by a median abdominal incision. The cavity was packed with a Mikulicz bag, by the side of which the handles of two pressure forceps, which had to be applied to the kidney where it was accidentally wounded, were allowed to emerge. The solid portion of the tumour was of about the size of a small adult head. The Mikulicz bag and pressure forceps were removed in 24 hours and the pedicle clamp 24 hours later. The patient made an uneventful recovery. Only a small quantity of clear serum was now discharging from the sinus.—Dr. Hobart also showed a Hatpin removed from the Urethra of a man, aged 22 years. He first tried to secure the point but failing in this he pushed the point through the skin until the head alone remained in the urethra. Next altering its direction he pushed the pin out through the meatus.—Dr. Henry Corby read notes of a case of Empyema treated by Estlander's Operation and showed the patient. In order to empty the cavity the patient with hips raised high, resting on his shoulders, was instructed to cough repeatedly in that position and the pus flowed out very freely. He was then put in a half-sitting posture and again repeatedly coughed, with similar results. This was done at each subsequent dressing and in five days the pus had completely disappeared, there being now only a little serum issuing from the minute sinus left. The patient had gained greatly in weight.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—A meeting of this society was held in the Faculty Hall on April 9th, Dr. J. Lindsay Steven, the Vice-President, being in the chair.—Mr. A. Ernest Maylard described the features of a case of Malignant Disease of the Duodenum surrounding the orifice of the common bile duct. The patient, a man, aged 39 years, was admitted to hospital suffering from jaundice, and dating the commencement of his illness—four months previously—to attacks of shivering with sense of prostration and with yellowness of the skin noted about ten days later. On admission the patient suffered from obstructive jaundice with marked pallor. No pain, tenderness, or tumour was noted in the region of the gall-bladder but a sense of resistance was elicited. About three weeks after admission an exploratory laparotomy was performed and the distended, tense gall-bladder was recumbent posture, as well as by using methods to obtain complete rest for the affected parts. By the aid of lantern views he demonstrated what he considered to be the best methods for securing that immobilisation and the prevention and correction of abnormal attitude in spine and hip disease. He was of opinion that in tuberculosis of bones and joints better results both as regards life and function were, as a rule, obtained by conservative than by operative means. In non-suppurative joint cases parenchymatous and intra-articular injections of iodoform gave good results. Mixed infection with pyococci was a complication to be dreaded and carefully guarded against; hence abscesses should not be opened but aspirated and then injected with iodoform, naphthol-camphor, or other modifying substances. He contrasted the method of incision and drainage with that of aspiration and injection and pointed out how it was almost impossible in many cases where there was a great deal of discharge, however careful one might be in the dressings, entirely to exclude other organisms. Mixed infection resulted in greatly delayed healing and frequent formation of fistula. With the closed method of treatment a cure was almost certain. He described his method of procedure in various cases, exhibited the syringe which he employed and explained its working, and enumerated various precautions which were necessary for success. It was essential always to choose a spot for puncture where the skin appeared to be quite normal; the skin must be thoroughly disinfected, and the needles and syringe sterilised; it was advisable also to soak the iodoform in carbolic solution before use. He preferred to use iodoform 10 per cent. in ether with sometimes a little glycerine or guaiacol. During the past three years he had treated 44 cases of "closed tuberculosis," in 34 of which bones or joints were affected, by injection or by aspiration and injection. These included cases of tuberculous periostitis of the jaw; spinal caries, with abscess in the neck; caries of rib, scapula and ilium; arthritis of elbow, wrist, ankle, hip and knee (several cases); six cases of psoas and two of lumbar abscess, &c. In three cases the treatment failed—two improved but died afterwards from pulmonary tuberculosis; in 41 the results were satisfactory. During that period no tuberculous abscess was opened and thus no patient was exposed to the risk of mixed infection. He considered that the results thus obtained were most encouraging and a great improvement on former methods and worthy of a more extended trial in the future. In advanced cases of bone disease with sinuses he had employed von Mosetig-Moorhof's method of clearing out the cavity and packing with iodoform paste with a considerable amount of success.—In the discussion which followed, Dr. G. Halley objected to the opinion expressed by other members that the results of the treatment were convincing as he considered that in many cases time could have been saved and the disease with more certainty eradicated by excision of the affected parts.—The majority of the meeting, however, were of opinion that the new method of treatment was a great advance on that of former days.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 7th, Mr. Russell Coombe, Vice-President, being in the chair.—Dr. A. W. F. Sayres reported a case of Aortic Aneurysm, exhibiting the patient and also radiographs taken by Dr. J. D. Harris. The patient was a man, aged 48 years. There was no definite history of syphilis. His health had been good until five years ago when he began to suffer from pains in the upper part of his chest above the heart. At this time it was pointed out to him that both radial pulses were absent. During the next three or four years the chief trouble was severe pain over both clavicles, passing up both sides of the neck to the back of the head and over both shoulders down the arms. For the last year this pain had not troubled him much but he had suffered from dyspnœa, at times severe, which was accompanied by stridor. In January, 1906, the patient had a severe attack. Dyspnœa was extreme; there was much stridor and he was cyanosed and he felt as if he would be suffocated. There was some dysphagia but he was able to swallow liquids freely. Laryngoscopic examination exhibited no paralysis of cords. The pupils were equal and acted to light. The trachea was markedly pushed back and there was an area of dulness with its centre at the left sterno-clavicular joint and pulsation was plainly visible here but no bruit could be detected. Tracheal tugging was not marked. Neither radial pulse could be felt. No marked sign of arterio-sclerosis was present. There was no loss of flesh. Radiographs showed marked shading in the region of the transverse arch of the aorta. For two and a half months the treatment consisted of five grains of potassium iodide, and for a month a modified Tufnell's diet was given. There were marked improvement, very little dyspnœa, and scarcely any pain. The following are interesting points in the case: (1) loss of both radial pulses; (2) cessation of pain; (3) absence of pressure on recurrent laryngeal and sympathetic nerves; (4) absence of œdema of the neck; and (5) improvement in pressure symptoms.—Mr. A. C. Roper and Mr. R. V. Solly reported a case of Cerebro-spinal Meningitis secondary to Middle-ear Disease. The patient, a stoker in the navy, aged 25 years, was admitted into hospital on Dec. 7th, 1905. In October a polypus had been removed from his left ear and a fortnight before admission he had been discharged from the naval hospital as fit for duty, but as he did not look well his commander gave him a short holiday. In a few days he was admitted suffering from severe pain, giddiness, and dimness of vision; severe vomiting had been present. There were some swelling and tenderness of the left side of the neck. No optic neuritis was present. The mastoid was trephined and a communication with the external auditory meatus was established but no pus was seen and no relief was obtained. Marked pyrexia of irregular type was present. The pulse was slow and full and there was free perspiration. Nystagmus was present, lateral and vertical. The pulse and respiration were markedly irregular. A blood count showed 33,000 leucocytes per cubic millimetre, with 82 per cent. of polymorphonuclears. Lumbar puncture was performed and a few drachms of fluid were removed. This was opalescent and contained an enormous proportion of polymorphonuclears; a very few lymphocytes, large and small, were also present. A few diplococci and some short, rather thick bacilli, negative to Gram, were also seen in stained films of centrifugalised fluid. A culture was made but proved sterile. The patient did not improve and died on the next day. Kernig's sign and increased plantar reflexes had been present. A post-mortem examination showed marked purulent meningitis at the base of the brain. No abscess was present. There was thrombosis in both petrosal sinuses. The petrous portion of the temporal bone (left) was soft and was easily chiselled away exposing a mass of pus and débris where cochlea and semicircular canals should be. There was marked sclerosis of the mastoid cells. Pus and granulating tissue passed into the aqueductus Fallopii. Films of pus at the base of the brain showed microscopically capsulated diplococci and many bacilli, some large and some small, and Gram-negative. Mr. Solly exhibited microscopical slides of films of the cerebro-spinal fluid and pus obtained post mortem. He pointed out the correspondence between the blood count and the lumbar puncture as regards the predominance of polymorphonuclears. The usual organism in cerebro-spinal meningitis after ear disease was the pneumococcus, but a lepto-meningitis due to the influenza bacillus occurred and it was possible that the bacilli present in the cerebro-spinal fluid were these. The French authorities, Widal, Labbé, and others, had especially studied the cytodiagnosis of cerebro-spinal fluid obtained by lumbar puncture, which was particularly useful in distinguishing tuberculous meningitis (where an excess of lymphocytes was present) from septic cerebro-spinal meningitis (where polymorphonuclears predominated), and also in distinguishing both of these forms of meningitis from conditions such as typhoid fever, where no cerebro-spinal meningitis was present and the fluid was normal.—Mr. B. Dyball reported a case of severe Erysipelas treated by antistreptococcic serum. A fortnight previously the patient had suffered from a peritonsillar abscess. The temperature was high and the rash extended all over the body, beginning in the forehead. Treatment consisted of a mixture of strychnine and cinchona and an ointment of ichthyol was applied. Four injections of antistreptococcic serum were given, three of ten cubic centimetres, each reducing the temperature and stopping the spread of the rash, and finally one of 20 cubic centimetres, which effected a complete cure. The patient later developed venous thrombosis and became completely bald. The antistreptococcic serum was not polyvalent.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on April 9th, Mr. F. Bowreman Jessett, the President, being in the chair.—Dr. H. Macnaughton-Jones read notes on the Use of Vioform as a Substitute for Iodoform.—Dr. A. E. Giles showed: 1. Uterine Myoma with Suppurating Carcinomatous Ovarian Cyst removed from

from the size of peas to that of beans. He regarded them as endotheliomata originating probably from the endothelium of the peritoneum.—Dr. Arthur N. Holmes read a paper on a case of Hernia of the Gravid Uterus through an old abdominal scar. The patient had become pregnant shortly after the operation and had noticed a lump protruding from the lower part of the abdomen; this swelling after the confinement almost disappeared. She again became pregnant, the lump steadily increasing, and circular ulcers formed where the clothes and thighs had rubbed. After delivery in November, 1903, the tumour remained, though smaller in size. On Dec. 22nd, 1905, she went to the Rotunda Hospital. On examination there was found a tumour springing from between the umbilicus and symphysis, which, falling forward, reached more than half-way down the front of the thigh. This proved to be the uterus and the fœtal movements were felt. The skin was very thin and large circular ulcers were distributed over its surface. Some of these extended to the uterine muscle. The patient stated positively that she was at full term and that labour pains were beginning. She delivered herself suddenly without any trouble of a live child who presented all the appearance of being up to full term. The weight was three and a half pounds and the length was 14 inches. The placenta was removed manually on accoun of hæmorrhage. Reduction of the uterus was impossible on account of the adhesions. The diminutive size of the child was thought to be due to the diminished blood-supply consequent on the abnormal position of the uterus and the constriction caused by the ring of the sac. The woman delivered herself and had no pain. The tumour was of about the size of a man's head. Dr. Purefoy told him that the woman was going about her work and was apparently well. The child died shortly afterwards from an attack of green diarrhœa.—Dr. Horne said that he had never seen a case of this kind. It was hard to conceive how the child was born through so great a constriction.—Dr. James S. Ashe read a paper entitled "Some Remarks on Uterine Suspension and Shortening Round Ligaments" (Adelaide Hospital Report, 1905). In it he showed a preference for the operation of suspension rather than for the shortening of ligaments.—Dr. Horne said that he had rarely seen any untoward results follow the use of pessaries, and if such did occur it was possible the pessaries had not been properly applied.—Sir Arthur Macan said that he rather favoured the use of pessaries. A woman came to him who had worn a pessary for eight years. She had no vaginitis and the pessary showed no signs of wear. If pessary treatment was at all beneficial it was preferable to operation.

GLASGOW MEDICO CHIRURGICAL SOCIETY.—A meeting of this society was held on April 6th, Dr. J. L. Steven, the President, being in the chair.—Dr. A. N. McGregor (for Dr. T. K Monro) showed a man, aged 40 years, on whom the operation of Epiplopexy had been performed nearly eight months previously for cirrhosis of the liver with ascites. The result was thoroughly satisfactory. Except that on one occasion, about two months ago, there was melæna, the patient had been perfectly well since the operation and feeling better indeed than he had done for 15 years previously. A considerable vein could now be seen running down from the scar to the left groin. The operation consisted simply in suture of the omentum to the anterior abdominal wall.—Dr. John W Findlay showed (for Dr. Monro) a patient who was the subject of Syringomyelia with the typical symptoms The loss of the senses of pain and temperature involved the upper part of the trunk, the upper limb, the neck and the scalp, all on the right side. It was noteworthy that there was loss also of muscular sensibility in the right arm, as tested by compression of the muscles and by faradism.—In the absence of Dr. Monro Dr. Findlay also described the clinical features of a case of Syringomyelia which was under observation in the Royal Infirmary some time ago. The patient died after a comparatively short residence, having been admitted at a late period of his disease and dying no doubt in consequence of exhaustion and septic poisoning from the formidable bed-sores which exposed several bones and discharged large quantities of pus The symptoms of syringomyelia were no longer distinctive at this stage, although the condition had been suspected a number of years previously.—Dr. Hugh McLaren showed sections of the Spinal Cord which contained one or more cavities extending through the great part of its length. The cavity was not simply a dilatation of the central canal although it communicated with it. Widespread sclerosis was also present.—Dr. W. F. Somerville read a paper on the Influence of High frequency Currents on the Surface Temperature of the Body, illustrated by charts He found that high-frequency currents produced a rise of temperature on the surface of the body varying with the dosage, the site chosen and the mode of application, by their action on the vaso-motor system producing increased peripheral circulation, and in some cases a dilatation of the deeper vessels also. The rise of temperature varied from 1·4° to 17·4° F.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on April 11th, Mr. Willmott H. Evans being in the chair.—Dr. Edward Stainer showed an Acneiform Eruption of the Face in a man, aged 24 years, who had had the eruption for four years. It had left an extraordinary amount of scarring and the possibility of its being acne varioliformis was discussed, but there were no lesions in the parts covered with hair, and this diagnosis was therefore dismissed. The general opinion was that it was a case of acne vulgaris with a wholly exceptional degree of scarring.—Mr. Evans showed a case of Linear Papillary Nævus in a little girl in whom the condition was congenital. The distribution was probably metameric rather than in the course of peripheral nerves, Mr. Evans pointing out that no peripheral nerve corresponded with the site of the eruption. The right shoulder, the upper arm, the forearm, and the back of the head had a linear streak extending to the cleft of the index and middle fingers. There was a small patch of similar character on the right half of the chin. Mr. Evans proposed to treat the condition with x rays.—Dr. E G. Graham Little showed a case of Lichen Planus Annulatus in a man who had had the disease as now present for four months. There was no itching. There were numerous small papules scattered chiefly over the abdomen and not very typical of lichen planus and there were several ring-shaped lesions on the lower part of the abdomen, the rings being of the size of a threepenny piece and constituted by small papules which had run together. On the buccal mucous membrane there was a patch of characteristic lichen planus and a less typical appearance in the form of a line of raised white epithelium on the mucous membrane both of the mouth and of the glans penis; in the latter case the line went entirely round the glans in a festooned wreath. A section of one of the papules from the abdomen showed the typical features of lichen planus.

Reviews and Notices of Books.

Clinical Diagnosis: the Bacteriological, Chemical, and Microscopical Evidences of Disease. By RUDOLF VON JAKSCH, M D. Fifth English edition, based upon the Fifth German edition, but containing additional matter and illustrations. Edited by ARCHIBALD E GARROD, M.D Oxon., F R.C P. Lond. London: Charles Griffin and Co. 1905. Pp. 602. Price 24s. net.

THE unsigned preface, presumably by the author, refers to the loss sustained by the premature death of Dr. J. Cagney who originally translated the volume, and to the work of Dr. A. E. Garrod who has revised the present translation and made many additions to the book. The general scope of this volume is too well known for it to stand in need of detailed description. In spite of its title it is concerned rather with the work of the laboratory than with that of the wards or of the bedside. The subtitle forms a truer description of the nature of the information here afforded and the time has come when it is recognised that this information is of incalculable service, although it does *not replace* clinical observation. In the present edition, within the limits defined by the subtitle, the volume is truly marvellous in the general accuracy with which it reflects all recent advances in methods of laboratory investigation. New intruments of precision are fully described and illustrated, while the results of the most recent researches are also presented in a condensed but an intelligible form. Attention is specially directed to the inclusion, by permission of the Royal Society of London, of a plate which shows forms of human trypanosoma and which is opened and drained. No gall-stones were found. In the second part of the duodenum a somewhat moveable tumour, apparently implicating the head of the pancreas and common bile duct, was found and as the tumour was considered to be inoperable it was decided to complete the operation as a cholecystotomy. A biliary fistula resulted but the jaundice became less marked and the general condition of the patient improved. He was sent to the convalescent home for some weeks and returned to hospital with the object of having a cholecyst-enterostomy performed as the fistula was still discharging bile, but without warning he suddenly collapsed and died a few hours after his re-admission.—Dr. John Anderson described the conditions met with at the post-mortem examination and showed the specimen of the tumour of the duodenum and microscopical preparations of the same. There was a moderate degree of jaundice and the organs were bile-stained. The heart muscle was soft and the right side was dilated. The growth, which was situated in the second part of the duodenum, presented the appearances of a spherical carcinomatous ulcer of three inches in diameter, involving the bile papilla, but the diverticulum of Vater was still patent. Above its relationship to the head of the pancreas the common bile duct was dilated, and there was slight dilatation of the duct of Wirsung. No evidence of tumour tissue was present in the head of the pancreas itself, but the lymphatic glands around the same were enlarged and were evidently the seat of malignant invasion. The bile ducts and portal branches in the liver were dilated but there were no malignant nodules present. The gall-bladder, though collapsed, was healthy in appearance.—Dr. T. K. Monro showed a specimen of Aneurysm of the Splenic Artery from a case of ulcerative endocarditis. The patient, a young man, aged 23 years, was admitted to hospital suffering from breathlessness on exertion, weakness, and pain in the chest and legs. During his residence in the wards he suffered from arthritis of the knees and irregular pyrexia. The heart was enlarged and at the apex A.S., V.S., and V.D. murmurs were heard and at the other cardiac areas V.S. and V.D. murmurs. The lungs were normal and the spleen, at first noted as normal, was afterwards made out to be enlarged. The urine was albuminous and there was anæmia of the secondary type. Sodium salicylate and antistreptococcic serum were both tried but failed to have effect. The bacteriological examinations were negative. At the necropsy the heart was found to be enlarged and there were large, almost cartilaginous, vegetations on the aortic cusps, and smaller warty vegetations on the mitral and tricuspid. Infarctions were present in the spleen and the splenic artery at its point of entrance into the organ showed the presence of an aneurysm of the size of a Tangerine orange and filled with blood clot.—Dr. A. M. Ramsay and Dr. Hugh Walker gave a clinical and pathological report on a case of Tuberculosis of the Uveal Tract and showed microscopical specimens from the same. The patient gave a history of good health up to six weeks before admission to hospital when he began to suffer from what he called inflammation of the eye and latterly of a swelling at the upper aspect of the corneo-scleral junction, which had a soft and yellowish-white appearance and the conjunctiva covering it was traversed by large varicose vessels. There was a bad tuberculous family history and as the eye became worse after admission it was enucleated. In addition to the extra-ocular mass a large-sized intra-ocular tuberculous tumour was present.—Dr John Patrick showed two brothers who suffered from Malocclusion of the Jaws. The only teeth which approximated were the back molars. The teeth of the lower jaw were somewhat larger and were situated external to those of the upper, while there was present a very high arch of the palate. The difficulty of explanation of the origin of the condition and of a means of treatment were commented upon.

Nottingham Medico-Chirurgical Society.—A meeting of this society was held on April 18th, Mr. T. J. Dabell, the President, being in the chair.—Dr. F. H. Jacob showed a married woman, aged 36 years, the subject of Paresis of the Third Cranial Nerve. Some improvement had taken place with large doses of potassium iodide.—Mr. W. Morley Willis read notes of a case of Mucous Colitis treated by Appendicostomy. The patient was a woman, aged 32 years, who had suffered for at least two years with loss of flesh, abdominal pain, and hard and scybalous motions; independently of fæcal stools she also passed blood, mucus, or membrane daily, and there was the train of neurotic symptoms usual in such cases. At the operation a month ago the appendix was brought out between the fibres of the external oblique muscle and fixed there, the projecting portion being shaved off three days later. A week after the operation lavage of the colon was begun, from two to three pints of soap and water being introduced through a small catheter, and no leakage had ever occurred from the stump of the appendix beyond a little moisture due to glandular secretion. Very great improvement had taken place in all the symptoms during the three weeks in which this measure was carried out daily, the fluid being retained for 20 minutes or longer before a natural evacuation followed. The patient had now developed a healthy appetite and had begun to take an intelligent interest in her life again. Mr. Willis pointed out that the disadvantages of a colotomy wound were entirely avoided and thought (as recently suggested by Sir W. H. Bennett) that the operation would also prove a serviceable one where there was great distension in cases of highly toxic peritonitis or pneumonia and for feeding purposes but did not anticipate that it would be of much real value in typhoid fever. There ought to be no difficulty, if necessary, in closing the fistula when the patient's health was thoroughly re-established.—The case was discussed by the President, Dr. C. H. Cattle, Dr. Jacob, Dr. W. Hunter, Mr. W. J. H. Hepworth, Mr. E. Powell, Dr. F. R. Mutch, Dr. W. Tibbles, and Mr. R. G. Hogarth, and Mr. Willis replied.—Dr. Jacob showed photographs of a patient suffering from Syphilitic Psoriasis of the Palm. Special interest arose from the fact that before any history of syphilis was forthcoming she had undergone at least three curettings for intractable metrorrhagia and the uterus was finally removed and was found to have undergone fibrotic or sclerotic changes.—Dr. W. T. Rowe showed a specimen of Primary Tuberculosis of the Intestine in a breast-fed infant, aged six and a half months. The child had had cow's milk for only two days and death was due to acute hæmorrhage from an ulcer. Since then the child's grandmother had come under treatment for pulmonary tuberculosis so that infection had most probably occurred from this source.—Dr. Cattle quoted a similar case in an adult and pointed out that both cases were in strict accordance with Koch's view as the infection was from human and not bovine sources.—Dr. Powell showed two specimens found in the post-mortem room of an asylum: 1. Primary Carcinoma of the Liver in a woman the subject of alcoholic dementia. The liver as a whole weighed seven and a half pounds and the disease was of a latent character until abdominal distension occurred a short time before death. 2. A Heart weighing 33¼ ounces. Great hypertrophy had occurred as the result of mitral and aortic stenosis, the latter orifice being so far occluded as only to admit a match.

Royal Academy of Medicine in Ireland: Section of Obstetrics.—A meeting of this section was held on April 6th, Sir Arthur V. Macan being in the chair.—Dr. Andrew J. Horne exhibited a Myoma of the Uterus showing Cystic and Calcareous Degeneration. The patient was aged 45 years, was the mother of six children, and had menstruated regularly.—Mr. E. Hastings Tweedy exhibited a specimen of Cancer of Both Ovaries. The patient was a woman, aged 21 years, who had been operated on in a hospital some weeks previously for an ascitic collection, supposed to be the result of tuberculous peritonitis. She entered the Rotunda Hospital, Dublin, five weeks afterwards in an apparently dying state and enormously distended by peritoneal dropsy. On opening the abdomen he found the intestines tucked up under the diaphragm and very adherent to each other; they, together with the entire peritoneum, were studded with coarsely granular masses, which he remarked at the time of the operation resembled endothelioma rather than tubercle. The ovaries appeared papillomatous and were both removed. The abdominal cavity was drained with five wicks of iodoform gauze in the hope that they would be the means of causing an adhesive peritonitis and so obliterating the weeping surfaces. For several days fluid escaped through the drains but this gradually became less and the patient left the hospital symptomatically cured and declaring that she was feeling better than she had done for two years. He had examined the patient that morning. Her abdomen was hard and the cancer seemed again advancing.—Dr. R. J. Rowlette, who examined the pathological condition of the parts removed, said that the tumours were of a nodular character, the nodules varying

from the size of peas to that of beans. He regarded them as endotheliomata originating probably from the endothelium of the peritoneum.—Dr. Arthur N. Holmes read a paper on a case of Hernia of the Gravid Uterus through an old abdominal scar. The patient had become pregnant shortly after the operation and had noticed a lump protruding from the lower part of the abdomen; this swelling after the confinement almost disappeared. She again became pregnant, the lump steadily increasing, and circular ulcers formed where the clothes and thighs had rubbed. After delivery in November, 1903, the tumour remained, though smaller in size. On Dec. 22nd, 1905, she went to the Rotunda Hospital. On examination there was found a tumour springing from between the umbilicus and symphysis, which, falling forward, reached more than half-way down the front of the thigh This proved to be the uterus and the fœtal movements were felt. The skin was very thin and large circular ulcers were distributed over its surface. Some of these extended to the uterine muscle. The patient stated positively that she was at full term and that labour pains were beginning. She delivered herself suddenly without any trouble of a live child who presented all the appearance of being up to full term. The weight was three and a half pounds and the length was 14 inches. The placenta was removed manually on account of hæmorrhage. Reduction of the uterus was impossible on account of the adhesions. The diminutive size of the child was thought to be due to the diminished blood-supply consequent on the abnormal position of the uterus and the constriction caused by the ring of the sac. The woman delivered herself and had no pain. The tumour was of about the size of a man's head. Dr. Purefoy told him that the woman was going about her work and was apparently well. The child died shortly afterwards from an attack of green diarrhœa —Dr. Horne said that he had never seen a case of this kind. It was hard to conceive how the child was born through so great a constriction.—Dr. James S Ashe read a paper entitled "Some Remarks on Uterine Suspension and Shortening Round Ligaments" (Adelaide Hospital Report, 1905). In it he showed a preference for the operation of suspension rather than for the shortening of ligaments.—Dr. Horne said that he had rarely seen any untoward results follow the use of pessaries, and if such did occur it was possible the pessaries had not been properly applied —Sir Arthur Macan said that he rather favoured the use of pessaries. A woman came to him who had worn a pessary for eight years. She had no vaginitis and the pessary showed no signs of wear. If pessary treatment was at all beneficial it was preferable to operation.

GLASGOW MEDICO CHIRURGICAL SOCIETY.— A meeting of this society was held on April 6th, Dr. J. L. Steven, the President, being in the chair.—Dr. A. N. McGregor (for Dr. T. K Monro) showed a man, aged 40 years, on whom the operation of Epiplopexy had been performed nearly eight months previously for cirrhosis of the liver with ascites. The result was thoroughly satisfactory. Except that on one occasion, about two months ago, there was melæna, the patient had been perfectly well since the operation and feeling better indeed than he had done for 15 years previously. A considerable vein could now be seen running down from the scar to the left groin. The operation consisted simply in suture of the omentum to the anterior abdominal wall.—Dr John W Findlay showed (for Dr. Monro) a patient who was the subject of Syringomyelia with the typical symptoms. The loss of the senses of pain and temperature involved the upper part of the trunk, the upper limb, the neck and the scalp, all on the right side. It was noteworthy that there was loss also of muscular sensibility in the right arm, as tested by compression of the muscles and by faradism.—In the absence of Dr. Monro Dr. Findlay also described the clinical features of a case of Syringomyelia which was under observation in the Royal Infirmary some time ago. The patient died after a comparatively short residence, having been admitted at a late period of his disease and dying no doubt in consequence of exhaustion and septic poisoning from the formidable bed-sores which exposed several bones and discharged large quantities of pus The symptoms of syringomyelia were no longer distinctive at this stage, although the condition had been suspected a number of years previously —Dr Hugh McLaren showed sections of the Spinal Cord which contained one or more cavities extending through the great part of its length. The cavity was not simply a dilatation of the central canal although it communicated with it. Widespread sclerosis was also present.—Dr. W. F. Somerville read a paper on the Influence of High frequency Currents on the Surface Temperature of the Body, illustrated by charts He found that high frequency currents produced a rise of temperature on the surface of the body varying with the dosage, the site chosen and the mode of application, by their action on the vaso-motor system producing increased peripheral circulation, and in some cases a dilatation of the deeper vessels also. The rise of temperature varied from 1·4° to 17·4° F.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on April 11th, Mr. Willmott H. Evans being in the chair.—Dr. Edward Stainer showed an Acneiform Eruption of the Face in a man, aged 24 years, who had had the eruption for four years. It had left an extraordinary amount of scarring and the possibility of its being acne varioliformis was discussed, but there were no lesions in the parts covered with hair, and this diagnosis was therefore dismissed. The general opinion was that it was a case of acne vulgaris with a wholly exceptional degree of scarring.—Mr. Evans showed a case of Linear Papillary Nævus in a little girl in whom the condition was congenital. The distribution was probably metameric rather than in the course of peripheral nerves, Mr. Evans pointing out that no peripheral nerve corresponded with the site of the eruption. The right shoulder, the upper arm, the forearm, and the back of the head had a linear streak extending to the cleft of the index and middle fingers. There was a small patch of similar character on the right half of the chin. Mr. Evans proposed to treat the condition with x rays.—Dr. E G. Graham Little showed a case of Lichen Planus Annulatus in a man who had had the disease as now present for four months There was no itching. There were numerous small papules scattered chiefly over the abdomen and not very typical of lichen planus and there were several ring-shaped lesions on the lower part of the abdomen, the rings being of the size of a threepenny piece and constituted by small papules which had run together. On the buccal mucous membrane there was a patch of characteristic lichen planus and a less typical appearance in the form of a line of raised white epithelium on the mucous membrane both of the mouth and of the glans penis; in the latter case the line went entirely round the glans in a festooned wreath. A section of one of the papules from the abdomen showed the typical features of lichen planus.

Reviews and Notices of Books.

Clinical Diagnosis: the Bacteriological, Chemical, and Microscopical Evidences of Disease. By RUDOLF VON JAKSCH, M D. Fifth English edition, based upon the Fifth German edition, but containing additional matter and illustrations. Edited by ARCHIBALD E GARROD, M D Oxon., F R.C P. Lond. London: Charles Griffin and Co. 1905. Pp. 602. Price 24*s*. net.

THE unsigned preface, presumably by the author, refers to the loss sustained by the premature death of Dr. J. Cagney who originally translated the volume, and to the work of Dr. A. E. Garrod who has revised the present translation and made many additions to the book. The general scope of this volume is too well known for it to stand in need of detailed description. In spite of its title it is concerned rather with the work of the laboratory than with that of the wards or of the bedside. The subtitle forms a truer description of the nature of the information here afforded and the time has come when it is recognised that this information is of incalculable service, although it does not replace clinical observation. In the present edition, within the limits defined by the subtitle, the volume is truly marvellous in the general accuracy with which it reflects all recent advances in methods of laboratory investigation. New intruments of precision are fully described and illustrated, while the results of the most recent researches are also presented in a condensed but an intelligible form. Attention is specially directed to the inclusion, by permission of the Royal Society of London, of a plate which shows forms of human trypanosoma and which is

opened and drained. No gall-stones were found. In the second part of the duodenum a somewhat moveable tumour, apparently implicating the head of the pancreas and common bile duct, was found and as the tumour was considered to be inoperable it was decided to complete the operation as a cholecystotomy. A biliary fistula resulted but the jaundice became less marked and the general condition of the patient improved. He was sent to the convalescent home for some weeks and returned to hospital with the object of having a cholecyst-enterostomy performed as the fistula was still discharging bile, but without warning he suddenly collapsed and died a few hours after his re-admission.—Dr. John Anderson described the conditions met with at the post-mortem examination and showed the specimen of the tumour of the duodenum and microscopical preparations of the same. There was a moderate degree of jaundice and the organs were bile-stained. The heart muscle was soft and the right side was dilated. The growth, which was situated in the second part of the duodenum, presented the appearances of a spherical carcinomatous ulcer of three inches in diameter, involving the bile papilla, but the diverticulum of Vater was still patent. Above its relationship to the head of the pancreas the common bile duct was dilated, and there was slight dilatation of the duct of Wirsung. No evidence of tumour tissue was present in the head of the pancreas itself, but the lymphatic glands around the same were enlarged and were evidently the seat of malignant invasion. The bile ducts and portal branches in the liver were dilated but there were no malignant nodules present. The gall-bladder, though collapsed, was healthy in appearance.—Dr. T. K. Monro showed a specimen of Aneurysm of the Splenic Artery from a case of ulcerative endocarditis. The patient, a young man, aged 23 years, was admitted to hospital suffering from breathlessness on exertion, weakness, and pain in the chest and legs. During his residence in the wards he suffered from arthritis of the knees and irregular pyrexia. The heart was enlarged and at the apex A.S., V.S., and V.D. murmurs were heard and at the other cardiac areas V.S. and V.D. murmurs. The lungs were normal and the spleen, at first noted as normal, was afterwards made out to be enlarged. The urine was albuminous and there was anæmia of the secondary type. Sodium salicylate and antistreptococcic serum were both tried but failed to have effect. The bacteriological examinations were negative. At the necropsy the heart was found to be enlarged and there were large, almost cartilaginous, vegetations on the aortic cusps, and smaller warty vegetations on the mitral and tricuspid. Infarctions were present in the spleen and the splenic artery at its point of entrance into the organ showed the presence of an aneurysm of the size of a Tangerine orange and filled with blood clot.—Dr. A. M. Ramsay and Dr. Hugh Walker gave a clinical and pathological report on a case of Tuberculosis of the Uveal Tract and showed microscopical specimens from the same. The patient gave a history of good health up to six weeks before admission to hospital when he began to suffer from what he called inflammation of the eye and latterly of a swelling at the upper aspect of the corneo-scleral junction, which had a soft and yellowish-white appearance and the conjunctiva covering it was traversed by large varicose vessels. There was a bad tuberculous family history and as the eye became worse after admission it was enucleated. In addition to the extra-ocular mass a large-sized intra-ocular tuberculous tumour was present.—Dr John Patrick showed two brothers who suffered from Malocclusion of the Jaws. The only teeth which approximated were the back molars. The teeth of the lower jaw were somewhat larger and were situated external to those of the upper, while there was present a very high arch of the palate. The difficulty of explanation of the origin of the condition and of a means of treatment were commented upon.

Nottingham Medico-Chirurgical Society.—A meeting of this society was held on April 18th, Mr. T. J. Dabell, the President, being in the chair.—Dr. F. H. Jacob showed a married woman, aged 36 years, the subject of Paresis of the Third Cranial Nerve. Some improvement had taken place with large doses of potassium iodide.—Mr. W. Morley Willis read notes of a case of Mucous Colitis treated by Appendicostomy. The patient was a woman, aged 32 years, who had suffered for at least two years with loss of flesh, abdominal pain, and hard and scybalous motions; independently of fæcal stools she also passed blood, mucus, or membrane daily, and there was the train of neurotic symptoms usual in such cases. At the operation a month ago the appendix was brought out between the fibres of the external oblique muscle and fixed there, the projecting portion being shaved off three days later. A week after the operation lavage of the colon was begun, from two to three pints of soap and water being introduced through a small catheter, and no leakage had ever occurred from the stump of the appendix beyond a little moisture due to glandular secretion. Very great improvement had taken place in all the symptoms during the three weeks in which this measure was carried out daily, the fluid being retained for 20 minutes or longer before a natural evacuation followed. The patient had now developed a healthy appetite and had begun to take an intelligent interest in her life again. Mr. Willis pointed out that the disadvantages of a colotomy wound were entirely avoided and thought (as recently suggested by Sir W. H. Bennett) that the operation would also prove a serviceable one where there was great distension in cases of highly toxic peritonitis or pneumonia and for feeding purposes but did not anticipate that it would be of much real value in typhoid fever. There ought to be no difficulty, if necessary, in closing the fistula when the patient's health was thoroughly re-established.—The case was discussed by the President, Dr. C. H. Cattle, Dr. Jacob, Dr. W. Hunter, Mr. W. J. H. Hepworth, Mr. E. Powell, Dr. F. R. Mutch, Dr. W. Tibbles, and Mr. R. G. Hogarth, and Mr. Willis replied.—Dr. Jacob showed photographs of a patient suffering from Syphilitic Psoriasis of the Palm. Special interest arose from the fact that before any history of syphilis was forthcoming she had undergone at least three curettings for intractable metrorrhagia and the uterus was finally removed and was found to have undergone fibrotic or sclerotic changes.—Dr. W. T. Rowe showed a specimen of Primary Tuberculosis of the Intestine in a breast-fed infant, aged six and a half months. The child had had cow's milk for only two days and death was due to acute hæmorrhage from an ulcer. Since then the child's grandmother had come under treatment for pulmonary tuberculosis so that infection had most probably occurred from this source.—Dr. Cattle quoted a similar case in an adult and pointed out that both cases were in strict accordance with Koch's view as the infection was from human and not bovine sources.—Dr. Powell showed two specimens found in the post-mortem room of an asylum: 1. Primary Carcinoma of the Liver in a woman the subject of alcoholic dementia. The liver as a whole weighed seven and a half pounds and the disease was of a latent character until abdominal distension occurred a short time before death. 2. A Heart weighing 33¼ ounces. Great hypertrophy had occurred as the result of mitral and aortic stenosis, the latter orifice being so far occluded as only to admit a match.

Royal Academy of Medicine in Ireland: Section of Obstetrics.—A meeting of this section was held on April 6th, Sir Arthur V. Macan being in the chair.—Dr. Andrew J. Horne exhibited a Myoma of the Uterus showing Cystic and Calcareous Degeneration. The patient was aged 45 years, was the mother of six children, and had menstruated regularly.—Mr. E. Hastings Tweedy exhibited a specimen of Cancer of Both Ovaries. The patient was a woman, aged 21 years, who had been operated on in a hospital some weeks previously for an ascitic collection, supposed to be the result of tuberculous peritonitis. She entered the Rotunda Hospital, Dublin, five weeks afterwards in an apparently dying state and enormously distended by peritoneal dropsy. On opening the abdomen he found the intestines tucked up under the diaphragm and very adherent to each other; they, together with the entire peritoneum, were studded with coarsely granular masses, which he remarked at the time of the operation resembled endothelioma rather than tubercle. The ovaries appeared papillomatous and were both removed. The abdominal cavity was drained with five wicks of iodoform gauze in the hope that they would be the means of causing an adhesive peritonitis and so obliterating the weeping surfaces. For several days fluid escaped through the drains but this gradually became less and the patient left the hospital symptomatically cured and declaring that she was feeling better than she had done for two years. He had examined the patient that morning. Her abdomen was hard and the cancer seemed again advancing.—Dr. R. J. Rowlette, who examined the pathological condition of the parts removed, said that the tumours were of a nodular character, the nodules varying

from the size of peas to that of beans. He regarded them as endotheliomata originating probably from the endothelium of the peritoneum.—Dr. Arthur N. Holmes read a paper on a case of Hernia of the Gravid Uterus through an old abdominal scar. The patient had become pregnant shortly after the operation and had noticed a lump protruding from the lower part of the abdomen; this swelling after the confinement almost disappeared. She again became pregnant, the lump steadily increasing, and circular ulcers formed where the clothes and thighs had rubbed. After delivery in November, 1903, the tumour remained, though smaller in size. On Dec. 22nd, 1905, she went to the Rotunda Hospital. On examination there was found a tumour springing from between the umbilicus and symphysis, which, falling forward, reached more than half-way down the front of the thigh. This proved to be the uterus and the fœtal movements were felt. The skin was very thin and large circular ulcers were distributed over its surface. Some of these extended to the uterine muscle. The patient stated positively that she was at full term and that labour pains were beginning. She delivered herself suddenly without any trouble of a live child who presented all the appearance of being up to full term. The weight was three and a half pounds and the length was 14 inches. The placenta was removed manually on accoun of hæmorrhage. Reduction of the uterus was impossible on account of the adhesions. The diminutive size of the child was thought to be due to the diminished blood-supply consequent on the abnormal position of the uterus and the constriction caused by the ring of the sac. The woman delivered herself and had no pain. The tumour was of about the size of a man's head. Dr. Purefoy told him that the woman was going about her work and was apparently well. The child died shortly afterwards from an attack of green diarrhœa.—Dr. Horne said that he had never seen a case of this kind. It was hard to conceive how the child was born through so great a constriction.—Dr. James S. Ashe read a paper entitled "Some Remarks on Uterine Suspension and Shortening Round Ligaments" (Adelaide Hospital Report, 1905). In it he showed a preference for the operation of suspension rather than for the shortening of ligaments.—Dr. Horne said that he had rarely seen any untoward results follow the use of pessaries, and if such did occur it was possible the pessaries had not been properly applied.—Sir Arthur Macan said that he rather favoured the use of pessaries. A woman came to him who had worn a pessary for eight years. She had no vaginitis and the pessary showed no signs of wear. If pessary treatment was at all beneficial it was preferable to operation.

GLASGOW MEDICO CHIRURGICAL SOCIETY.—A meeting of this society was held on April 6th, Dr. J. L. Steven, the President, being in the chair.—Dr. A N McGregor (for Dr. T. K. Monro) showed a man, aged 40 years, on whom the operation of Epiplopexy had been performed nearly eight months previously for cirrhosis of the liver with ascites. The result was thoroughly satisfactory. Except that on one occasion, about two months ago, there was melæna, the patient had been perfectly well since the operation and feeling better indeed than he had done for 15 years previously. A considerable vein could now be seen running down from the scar to the left groin. The operation consisted simply in suture of the omentum to the anterior abdominal wall.—Dr. John W Findlay showed (for Dr. Monro) a patient who was the subject of Syringomyelia with the typical symptoms. The loss of the senses of pain and temperature involved the upper part of the trunk, the upper limb, the neck and the scalp, all on the right side. It was noteworthy that there was loss also of muscular sensibility in the right arm, as tested by compression of the muscles and by faradism.—In the absence of Dr. Monro Dr. Findlay also described the clinical features of a case of Syringomyelia which was under observation in the Royal Infirmary some time ago. The patient died after a comparatively short residence, having been admitted at a late period of his disease and dying no doubt in consequence of exhaustion and septic poisoning from the formidable bed-sores which exposed several bones and discharged large quantities of pus. The symptoms of syringomyelia were no longer distinctive at this stage, although the condition had been suspected a number of years previously.—Dr Hugh McLaren showed sections of the Spinal Cord which contained one or more cavities extending through the great part of its length. The cavity was not simply a dilatation of the central canal although it communicated with it. Widespread sclerosis was also present.—Dr. W. F. Somerville read a paper on the Influence of High frequency Currents on the Surface Temperature of the Body, illustrated by charts. The child died shortly afterwards from an attack of green diarrhœa.—Dr. Horne said that he had never seen a case of this kind. It was hard to conceive how the child was born through so great a constriction.—Dr. James S. Ashe read a paper entitled "Some Remarks on Uterine Suspension and Shortening Round Ligaments" (Adelaide Hospital Report, 1905). In it he showed a preference for the operation of suspension rather than for the shortening of ligaments.—Dr. Horne said that he had rarely seen any untoward results follow the use of pessaries, and if such did occur it was possible the pessaries had not been properly applied.—Sir Arthur Macan said that he rather favoured the use of pessaries. A woman came to him who had worn a pessary for eight years. She had no vaginitis and the pessary showed no signs of wear. If pessary treatment was at all beneficial it was preferable to operation.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 6th, Dr. J. L. Steven, the President, being in the chair.—Dr. A. N. McGregor (for Dr. T. K. Monro) showed a man, aged 40 years, on whom the operation of Epiplopexy had been performed nearly eight months previously for cirrhosis of the liver with ascites. The result was thoroughly satisfactory. Except that on one occasion, about two months ago, there was melæna, the patient had been perfectly well since the operation and feeling better indeed than he had done for 15 years previously. A considerable vein could now be seen running down from the scar to the left groin. The operation consisted simply in suture of the omentum to the anterior abdominal wall.—Dr. John W. Findlay showed (for Dr. Monro) a patient who was the subject of Syringomyelia with the typical symptoms. The loss of the senses of pain and temperature involved the upper part of the trunk, the upper limb, the neck and the scalp, all on the right side. It was noteworthy that there was loss also of muscular sensibility in the right arm, as tested by compression of the muscles and by faradism.—In the absence of Dr. Monro Dr. Findlay also described the clinical features of a case of Syringomyelia which was under observation in the Royal Infirmary some time ago. The patient died after a comparatively short residence, having been admitted at a late period of his disease and dying no doubt in consequence of exhaustion and septic poisoning from the formidable bed-sores which exposed several bones and discharged large quantities of pus. The symptoms of syringomyelia were no longer distinctive at this stage, although the condition had been suspected a number of years previously.—Dr. Hugh McLaren showed sections of the Spinal Cord which contained one or more cavities extending through the great part of its length. The cavity was not simply a dilatation of the central canal although it communicated with it. Widespread sclerosis was also present.—Dr. W. F. Somerville read a paper on the Influence of High frequency Currents on the Surface Temperature of the Body, illustrated by charts. He found that high-frequency currents produced a rise of temperature on the surface of the body varying with the dosage, the site chosen and the mode of application, by their action on the vaso-motor system producing increased peripheral circulation, and in some cases a dilatation of the deeper vessels also. The rise of temperature varied from 1·4° to 17·4° F.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on April 11th, Mr. Willmott H. Evans being in the chair.—Dr. Edward Stainer showed an Acneiform Eruption of the Face in a man, aged 24 years, who had had the eruption for four years. It had left an extraordinary amount of scarring and the possibility of its being acne varioliformis was discussed, but there were no lesions in the parts covered with hair, and this diagnosis was therefore dismissed. The general opinion was that it was a case of acne vulgaris with a wholly exceptional degree of scarring.—Mr. Evans showed a case of Linear Papillary Nævus in a little girl in whom the condition was congenital. The distribution was probably metameric rather than in the course of peripheral nerves, Mr. Evans pointing out that no peripheral nerve corresponded with the site of the eruption. The right shoulder, the upper arm, the forearm, and the back of the head had a linear streak extending to the cleft of the index and middle fingers. There was a small patch of similar character on the right half of the chin. Mr. Evans proposed to treat the condition with x rays.—Dr. E. G. Graham Little showed a case of Lichen Planus Annulatus in a man who had had the disease as now present for four months. There was no itching. There were numerous small papules scattered chiefly over the abdomen and not very typical of lichen planus and there were several ring-shaped lesions on the lower part of the abdomen, the rings being of the size of a threepenny piece and constituted by small papules which had run together. On the buccal mucous membrane there was a patch of characteristic lichen planus and a less typical appearance in the form of a line of raised white epithelium on the mucous membrane both of the mouth and of the glans penis; in the latter case the line went entirely round the glans in a festooned wreath. A section of one of the papules from the abdomen showed the typical features of lichen planus.

Reviews and Notices of Books.

Clinical Diagnosis: the Bacteriological, Chemical, and Microscopical Evidences of Disease. By RUDOLF VON JAKSCH, M.D. Fifth English edition, based upon the Fifth German edition, but containing additional matter and illustrations. Edited by ARCHIBALD E. GARROD, M.D. Oxon., F.R.C.P. Lond. London: Charles Griffin and Co. 1905. Pp. 602. Price 24s. net.

THE unsigned preface, presumably by the author, refers to the loss sustained by the premature death of Dr. J. Cagney who originally translated the volume, and to the work of Dr. A. E. Garrod who has revised the present translation and made many additions to the book. The general scope of this volume is too well known for it to stand in need of detailed description. In spite of its title it is concerned rather with the work of the laboratory than with that of the wards or of the bedside. The subtitle forms a truer description of the nature of the information here afforded and the time has come when it is recognised that this information is of incalculable service, although it does not replace clinical observation. In the present edition, within the limits defined by the subtitle, the volume is truly marvellous in the general accuracy with which it reflects all recent advances in methods of laboratory investigation. New intruments of precision are fully described and illustrated, while the results of the most recent researches are also presented in a condensed but an intelligible form. Attention is specially directed to the inclusion, by permission of the Royal Society of London, of a plate which shows forms of human trypanosoma and which is

taken from the reports of the Commission on Sleeping Sickness. In the text relating to this subject an amusing misprint occurs; by the unfortunate insertion of a comma the identity of a physician is obscured and a surgeon is credited with having made certain unexpected recommendations (*vide* p. 80). As a rule, however, the new material, which is included in square brackets and is apparently the work of the editor, is concise and serviceable; frequently, though not invariably, it represents the results of his own observations. A word of gratitude must be assigned to the bibliography, both for its completeness and for its arrangement in 70 pages at the end of the volume in divisions which correspond with the different chapters. The value of the book as a work of reference would be increased if a list of authorities arranged alphabetically could be added at the next revision; the numbers in the bibliography indicate the order in which the various statements are referred to in the text and accordingly much time may be expended before the reader can be satisfied that the work of any particular observer has or has not been duly noticed. Meanwhile congratulations are due to the editor for the great trouble that he has taken to render the volume before us so superior to the last German edition; he has incorporated much that must in due season be added by Professor von Jaksch when preparing a new German edition and a certain feeling of satisfaction results from consulting a book, made in Germany, which has been improved upon in its preparation for English readers.

A Text-book on Plague. By Dr. TOHIU ISHIGAMI, Superintendent, Bacteriological Institute, Osaka, Japan. Revised by Professor SHIBASABURO KITASATO. Translated, enlarged, and illustrated with Pathogenic Horticulture by DONALD MACDONALD, M.B., C.M. Glasg. With 152 illustrations and three chromo-lithographic plates. Melbourne: William Ramsay. 1905. Pp. 180. Price 1 guinea.

THE author was induced to write this interesting work, embodying the results of his personal experience on plague, as he found that no book had ever been written on the subject in Japan, and as the disease was tending to become epidemic in Kobé and Osaka medical practitioners there were not infrequently in the dark as to its proper clinical treatment. The work evidently met the growing demand for such a book, for the first edition was soon out of print, whilst a second revised edition also followed the course of the first.

The book opens with a definition and summarised history of plague. The endemic regions of the disease are next enumerated—viz., the foot of the Himalayas, Asir in Arabia, Mesopotamia in Asia Minor, Yunnan and Thibet in North China, and Kisiba in Western Africa and the neighbourhood of Uganda. The author then tells the story of the biology of the plague bacillus, for the discovery of which medical science is indebted to the acumen of his fellow countryman Professor Kitasato. The special characteristics of the bacillus are fully given and the comparative effects of various chemical agents on its vitality are narrated. Dr. Markl's investigations on the toxin of the bacillus are then noted. The author next passes on to consider the extra-corporeal existence of the bacillus in water, soil, dust, food and drink, the urine, and in pieces of cloth and other materials.

With respect to the relation of the disease to insects and rats Professor Kitasato and others have shown that flies, mosquitoes, fleas, ants, bugs, rats, and mice are closely connected with plague epidemics. The insects are believed to invade plague-infected rats and disseminate the infection through sucking their infected blood. Should the insects come in contact with a human body they inoculate it either by stinging or biting. Professor Okada showed also that insects, especially flies, become infected and die as soon as they have tasted a liquid containing plague bacilli. Should a rat eat these dead flies it becomes infected and when that rat dies other rats will prey upon its infected corpse and so an epidemic breaks out amongst them. Professor Okada asserts, therefore, that the insects first become infected and subsequently the rats through eating such insects. Also, since the dejecta of such insects contain a large number of the plague bacilli, there is every opportunity offered for rats and human beings to be infected with the same.

As regards the portals through which the bacillus invades the human body there are three principal ones—namely, wounds, the respiratory system, and the digestive system, and of these the principal one is held to be a wound of the mucous surface or of the skin. The disease was, according to the experience in Formosa and Hong Kong, far more prevalent amongst the poor Chinese who go about barefooted than amongst the British or Japanese soldiers who wear boots and stockings. The post-mortem appearances, macroscopical and microscopical, are next given and then the author passes on to the symptoms. He enumerates five varieties of the disease—viz., the bubonic, pneumonic, intestinal, inoculative, and minor plague or pestis minor. With respect to the pneumonic type, the author shows how liable it is to be mistaken for croupous pneumonia unless special care be taken. The various sequelæ that may be observed are noted; these belong chiefly to the nervous system. Gangrene of the lung may also occur. Respecting prognosis the bubonic variety has the best, whilst the pneumonic form has little prospect of recovery. The acute cerebral type of the disease is invariably fatal.

A valuable chapter on the diagnosis of the affection is given, the diseases for which it may be mistaken being simple infective adenitis, pneumonia, enteric fever, and simple meningitis. In all difficult cases the diagnosis of the disease has to be made by the finding of the bacillus in the sputum, evacuations, blood, or urine, and the method to be followed is clearly described. Respecting the prophylaxis of plague the various measures are considered under the heads of (*a*) preventive measures, e.g., inspection of trains and isolation, conveyance of patients, and quarantine of vessels; (*b*) the treatment of the bacillus by chemicals; (*c*) the treatment of rats; and (*d*) prophylactic inoculation and serum therapy. Dr. Ishigami holds that amongst the remedial measures the most essential procedure is the early extraction of the affected gland, as this exterminates the very incubator of infection. Serum therapy would appear to be of no avail in pneumonic plague. Lastly, very valuable directions are given concerning the practical nursing of the cases.

The author of this very complete work modestly apologises in his preface for its incompleteness, but we can assure him that no such apology was necessary. The translation has been very well carried out by Dr. MacDonald.

The Sanitation of Armies on Active Service in the Field. By THOMAS F. DEWAR, M.D. Aberd., B.Sc. Edin. Arbroath: T. Buncle and Co. 1906.

WE have received a copy of this really valuable little production, apparently intended for private circulation, consisting of less than 100 pages. We have read it with much interest and advantage and therefore hasten to call our readers' attention to it. The author of this essay states that the subject matter, so far as it embodies personal observation, is based upon an extensive and a very varied experience, partly in the combatant ranks and partly in the medical service, in the recent war in South Africa. This, we may parenthetically remark, imparts a broadmindedness and practical aim to his method of handling his subject. He explains that the delay in its preparation has been due to the mass of material bearing upon the medical aspects of that war which demanded consideration and review together with other causes. Be this as it may, he has, in our opinion, produced a useful, well-considered, and up-to-date little work. It strikes us as being full of well selected and condensed information but it is not a mere compilation, for there is a running commentary of independent and, for the most part, of wise and sagacious observations. An ample list of references and authorities consulted adds to the usefulness of the essay.

LIBRARY TABLE.

The Edinburgh Stereoscopic Atlas of Anatomy. Edited by DAVID WATERSTON, M.A., M.D. Edin., F.R.C.S. Edin., F.R.S. Edin., Lecturer and Senior Demonstrator in the Department of Anatomy, University of Edinburgh. Section IV. 51 plates. London and Edinburgh: T. C. and E. C. Jack. 1906. Price £1 5s. net each section.—We have already indicated, when reviewing former sections of this Atlas, what we consider to be the advantages and what the shortcomings of the stereoscopic method as applied to anatomical illustration. The fourth section of the Edinburgh Atlas worthily sustains its reputation; it includes 51 views, for all of which new dissections have been employed and although we must say that we think that some of these have a somewhat unfinished appearance, since they seem to lack those final touches which make all the difference between a clean and a ragged specimen, yet they are admirably designed for the purposes in view. 25 of the views have been devoted to the upper limb, 16 illustrate the topographical anatomy of the perineum and pelvis, whilst ten illustrate the lumbar region and the positions of the viscera of the abdomen and thorax as seen from behind. The section contains some reproductions of photographs of very great interest and practical utility, in particular those which illustrate the abdominal and thoracic viscera from behind and also those which show the relations of the rectum and of some of the pelvic viscera in the female. These will be studied with interest and profit alike by the student of anatomy and the surgeon: they convey in a very real manner a knowledge of important visceral relations. The views of the surface anatomy of the arm also strike us as being remarkably good.

Essentials of Surface Anatomy. By CHARLES R. WHITTAKER, L.R.C.S., L.R.C.P. Edin., L.F.P.S. Glasg., Demonstrator of Anatomy, Surgeons Hall, Edinburgh. London: J. and A. Churchill. 1906. Pp 40. Price 2s. 6d. net.—This small volume contains a concise and an accurate *précis* of the main facts of human surface anatomy. The information is conveyed in a series of brief paragraphs, the contents of which are indicated by marginal notes. The arrangement adopted is regional, with the exception that blood-vessels and nerves are considered in special sections—a plan of distinct advantage from the student's point of view. The volume is not illustrated but is interleaved for additional notes. We agree with the author that for a quick revision of the salient points in surface marking the volume will amply suffice.

The University of Missouri Studies, Science Series, Vol. I., No. 1. Topography of the Thorax and Abdomen By PETER POTTER, Associate Professor of Anatomy, St. Louis University; sometime Instructor of Anatomy, University of Missouri. Published by the University. August, 1905. Price $1 50.—We congratulate Professor Potter on the painstaking piece of research which is here presented. The contribution deals with the topographical anatomy of the thorax and abdomen and embodies a minute description and rec[illegible]ion of a trunk studied by means of serial sections. The study is of great interest, since the author carefully compares his results with those of other authorities on the subject. The illustrations are carefully prepared and comprise no less than 35 plates which show not only the sections as they appeared when prepared but also the projections of the various viscera on the surface of the body. The author has set a high standard for his successors to emulate.

Ceylon: Administrative Reports, 1904. Part IV., Education, Science, and Art. Medical Report by Sir ALLAN PERRY, M.D.Durh., D.P.H. R.C.P.&S. Lond., Principal Civil Medical Officer and Inspector-General of Hospitals. Pp. 78.—This report contains a most comprehensive account of the medical history of the island of Ceylon during 1904. From it we learn that the chief infectious diseases were cholera, of which there were 7 cases with 4 deaths; small-pox, with 10 cases and 2 deaths; malaria, with 5288 cases and 75 deaths; and enteric fever, with 341 cases and 70 deaths. Compared with the numbers of the previous year, malaria was the only disease that showed an increase in its incidence. The cases of cholera did not originate in the island but were due to the infection in the s.s. *Torridge* which arrived in Colombo harbour. The malarial cases occurred in two distinct and serious epidemics, to inquire into which a commission was appointed. Many insanitary areas favourable for the breeding of mosquitoes were found. Dysentery supplied 2111 cases with 478 deaths, the total number being considerably less than in 1903. In regard to leprosy it is noted that Dr. Rost's leprolin serum was used "with very satisfactory results in three cases." Sir Allan Perry avows himself a follower of Mr. J. Hutchinson in the belief that parangi or yaws is syphilis and states that his officers have been instructed to treat these cases more rigorously with antisyphilitic measures. It will be interesting to note in the next report the results of this measure. The report of Dr. Aldo Castellani is an especially interesting one, embracing as it does sections on the various bacteriological examinations carried out during the year. The portion dealing with typhoid fever is very complete; his remarks on the great value of Widal's reaction and on the bacteriological examination of the stools and the urine and the search for the typhoid bacillus in the blood are full of interest. Dysentery also has been investigated by this observer most thoroughly and he has prepared a polyvalent vaccine for dysentery and para-dysentery which is harmless and which, although not advisable for use in ordinary cicumstances, might be useful in the case of a severe epidemic. Dr. Castellani prepares the anti-dysentery vaccine in peptone water. The blood of the inoculated person agglutinates the bacillus dysentericus of Kruse from 24 to 48 hours after the inoculation; the immunisation passes off in a few weeks. Dr. Castellani also determined the presence of three forms of dysentery; he found that ipecacuanha had no effect on the amœbic variety. The results obtained from the surgical operations performed were highly satisfactory, especially in the General Hospital, Colombo. In all there were 2733 operations, with only 46 deaths. Of these the Colombo Hospital contributed, under Dr. F. T. Garvin, 600 operations, with only 15 deaths, or a mortality of 2·5 per cent. His list includes several interesting cases, such as amputation of the hip by the Furneaux-Jordan method, for compound comminuted fracture of the femur with subsequent necrosis, the patient making an excellent recovery. He also reports a remarkable case of chronic intestinal obstruction where fæcal matter had not been passed for a fortnight. Left inguinal colotomy was performed. The patient at the time of the writing of the report was still in hospital but his recovery seemed to be assured. Space forbids us to enter more fully into this valuable report which reflects the greatest credit on all concerned in the medical and surgical work of Ceylon.

JOURNALS AND MAGAZINES.

School.—In the March and April numbers of *School* Mr. Sydney F. Walker describes in much detail various systems of warming and ventilating school buildings. After a brief explanation of the terms combustion, radiation, convection, and latent heat and of the production of draughts in rooms he gives particulars of a modification of the time-honoured open fireplace. In this the whole of the lower part of the chimney and the hearth is formed of glazed tiles, the bottom of the grate being raised from the floor, with an air space beneath. The hot gases and smoke from the fire pass up an iron flue inside the chimney, while air brought from outside the room is carried over the flue, the warmed air being delivered into the room just below the chimney breast. This arrangement provides a supply of warmed air constantly passing into the room. Hot-air furnaces are briefly mentioned and the danger of fire in connexion with them is noted. Heating by gas, either with the ordinary illuminating flame or with the Bunsen flame, is next taken up, after which come stoves containing a supply of coke or anthracite in a hopper from which the fire is automatically replenished. With regard to oil fuel Mr. Walker says that a good oil stove by a good maker, when properly attended to, is very useful. Heating by hot water circulating in flow and return pipes is then discussed and is said to be much the best for small areas. Where there is a steam-engine on the premises the waste steam from it may be used very economically for heating purposes and steam heating has the advantage that steam may be carried for a considerable distance in comparatively small pipes. Steam, however, may overheat the radiators through which it passes and cause an unpleasant smell by its action on dust lodged there.

Man.—In the April number of *Man* Dr. W. L. H. Duckworth gives a description, with four photographic views, of an artificially deformed adult skull found in Sarawak, Borneo, and now in the anatomical museum of the University of Cambridge. Mr. C. H. Read writes on the study of anthropology at the Universities of Oxford and London, expressing much satisfaction at the establishment at the former university of a diploma in anthropology.

STANDARDISATION OF DISINFECTANTS.

IN October, 1903, the Council of the Royal Sanitary Institute appointed a special committee, consisting of Mr. A. Wynter Blyth, Dr. C. Childs, Lieutenant-Colonel R. H. Firth, R.A.M.C., and Dr. Samuel Rideal, to inquire into the desirability of establishing a standard bacteriological method for determining the efficiency of disinfectants. The following additional experts were subsequently added to the committee: Dr. F. W. Andrewes (St. Bartholomew's Hospital), Professor Sheridan Delépine (Manchester), Mr. Walter Hills (representing the Pharmaceutical Society), Dr. E. Klein (St. Bartholomew's Hospital), Dr. Allan Macfadyen (Lister Institute of Preventive Medicine), Dr. James Ritchie (Oxford), Professor C. Hunter Stewart (Edinburgh), Professor G. Sims Woodhead (Cambridge), and Colonel J. Lane Notter, R.A.M.C., chairman of Council, *ex-officio*.

During the last two years this committee has held a large number of meetings to consider the question referred to it and numerous experiments have been carried out under the direction of the committee to aid the committee in coming to a decision. In the Journal of the Institute, vol. xxvii., No. 1, is published a report of experiments made on behalf of the committee and submitted to it by Colonel Firth and Dr. Allan Macfadyen, and it is proposed to publish in No. 5 a contribution from Professor Delépine on the "thread method."

The following report of the committee has been approved and adopted by the Council:—

Report of the Disinfectant Standardisation Committee.

1. The committee are of opinion that no one method of testing disinfectants can indicate their relative values under every possible condition. These must be specially determined for the given case required, and where penetration is important a "thread method" is indicated.

2. For general purposes, on account of its simplicity of working, the committee recommend the "drop method" as described in the *Journal of the Royal Sanitary Institute*, vol. xxiv. (1903), page 424.

The test to be carried out with pure broth cultures of the bacillus typhosus, using sterilised distilled water as the diluent of the disinfectant.

All nutrient broth to have a constant reaction of + 15.

Where special conditions exist which may interfere with the activity of the disinfectant the consumer should be advised to call for the same conditions to be embodied in the test.

(Signed) A. WYNTER BLYTH, Chairman.

April 9th, 1906.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 26th, 1828.

LONDON MEDICAL SOCIETY.

April 21, 1828.

Dr. WILLIAMS in the Chair.

THE important nature of the subject brought before the Society this evening, produced a very full attendance of the members.

DR. CLUTTERBUCK pointed out, in a forcible manner, the disadvantages and impediments which at present exist in the cultivation of the science of anatomy; he observed, that at the time he was a pupil, subjects could be procured at the price of two guineas; whilst at the present time, twenty guineas, or more, are paid, and the bodies are obtained with the greatest difficulty. The consequence of this, Dr. Clutterbuck remarked, is, that students, with limited means, omit the study of anatomy, whilst others go abroad, where subjects are readily procured, and at a cheap rate. The worthy Doctor concluded by moving, that a petition which had been drawn up by the council, and intended to be presented to the Commons, should be read. ......[1]

At the conclusion of the evening, a kind of conversational debate ensued, on the best means of supplying the schools of anatomy with subjects.

Mr. S. WRAY stated, that it was his conviction, Parliament would give no remedy, and that medical men should themselves set an example, by giving up their own bodies for the purposes of dissection, and thus Mr. Wray argued, the way would be paved, as it were, towards diminishing the prejudices of the public.

Mr. LAMBERT met these opinions by observing, that the notion of medical men giving up their own bodies, which had been trumpeted forth through many of the public papers, arose from a mistaken and narrow view of the subject. It was admitted on all sides, that no injury is done to the person dissected; the only injury committed, being upon feelings of the relatives, or friends, of the deceased; hence, the proposition was self-evident, that if the person submitted to dissection, had no friends or relatives, then no injury was sustained. He, Mr. Lambert, was perfectly willing that his body after death should be dissected; but he could not forget, that there were those near and dear to him, whose feelings would be outraged, and this injury he had no right to inflict. Mr. Lambert further remarked, that the annual amount of unclaimed bodies in the metropolis, as could readily be proved, would amply suffice for the supply of the anatomical schools; this appeared to him the only means that could possibly be adopted; to talk of diminishing the prejudices of surviving relatives, was, in his estimation, idle.

Mr. KINGDON concurred with Mr. Lambert, with respect to dissecting unclaimed bodies; but, at the same time, he thought the public feeling might well be consulted, by making it compulsory, as in France, to give Christian burial to the remains of the bodies, after the purposes of dissection had been served.

---

[1] The wording of the petition and some discussion relating thereto which fill up this lacuna have not been transcribed.

THE LANCET.

LONDON: SATURDAY, APRIL 28, 1906.

The Apathy of Londoners with regard to their Hospitals.

IT would be difficult to overstate the service done to the hospitals of London by members of the Royal Family, a service attested over a series of years and most recently by the report of the proceedings at the annual meeting of KING EDWARD'S Hospital Fund for London. Even in the course of his progress through India the PRINCE of WALES, in his letter read by the Duke of FIFE to the same meeting, shows that he had in full remembrance the details of the work done by KING EDWARD'S Fund and shared the confidence inspired by the work on the income of the year. For from the point of view of the Fund as a money collecting agency these results are most encouraging. The Fund received in the course of 1905 no less than £361,068. The larger share of this, it is true, represents money meant to be invested, but Lord ROTHSCHILD said, in submitting the accounts to the meeting, that they might take £123,862 as representing the normal annual receipts and that this was some £20,000 in excess of the expenditure. The eloquence of such figures seems unanswerable, the more so as they imply confidence all round. We cannot but admire the energy and persistence shown by the League of Mercy, represented ably by Sir WILLIAM COLLINS, which in the same year raised by its laborious methods £15,000, a thousand more than in the previous year, and which in the seven years of its existence has contributed to the Fund no less than £61,000. The League of Mercy is supposed to deal with the poorer sort of givers, from whom it is scarcely reasonable to expect much in the way of help. After all it is on the rich and the comfortable that voluntary hospitals must rely if charity itself is not to fail and our vaunted civilisation not to be discredited. Men like GUY should be plentifully forthcoming in this age if we are not 'degenerating in *morale* and in true and reasonable care for others It is a hopeful sign that the KING and his heir give proof that it is possible to be surrounded with luxury and yet most sympathetic with the humbler classes whose life problems are complicated with grave sickness or accident.

It may well be gratifying to those in charge of this successful Fund that many of the rich cast subscriptions into their treasury, bringing the income for the year up to the handsome sum already named and enabling investments to be made which will secure to the Fund henceforth a permanent income of £50,000 and an annual distribution of over £120,000. The munificent gift by Lord MOUNT STEPHEN of £200,000—the second of its proportions—is worthy of special mention. It raises our conception of what might happen any week in the way of relief to anxious hospital authorities if his example should become infectious. And we see no reason why it should not become so, while every argument in favour of such munificence becomes daily stronger. For we must not forget in this just praise of what has been achieved by KING EDWARD'S Fund and its sister funds, the Metropolitan Hospital Sunday and Saturday Funds, that with all their growth and success the cry for help from almost every hospital becomes weekly more anxious and acute, implying a burden which threatens to become intolerable and to imperil the voluntary system of hospital support which has hitherto been little less than a national glory. Adverse balances at the bankers and over-drafts and irksome mortgages seem to multiply at the hospitals even while the great central funds report year by year an increasing income. The problem is something like the fiscal problem of the nation—a constant report of expanding trade and national income on the one hand, with a constant complaint of increasing impecuniosity on the part of the majority of the nation on the other. It is only necessary to read the advertising columns of the newspapers or to study the reports of individual hospitals to see how general and how acute is the difficulty experienced by treasurers and committees of voluntary hospitals in making ends meet. And it is only justice to the executives of the great hospital funds, which supply approximately £200,000 a year to our metropolitan hospitals, to say that they fully recognise the fact that with all their success individual institutions are more and more embarrassed. But this fact, so plain and so ominous for our readers who know the circumstances, must escape the knowledge of the average Londoner, or how shall we account for his apathy? For which reason we are grateful to the Duke of FIFE for speaking very plainly at the annual meeting of KING EDWARD'S Fund upon this exact topic. "There is one thing," he said, "which nothing seems able to overcome, and that is the apathy of Londoners with regard to their hospitals. The great majority of them do not subscribe and the plain truth is that the London hospitals are maintained by a small number of charitable people."

The facts justify this plain and powerful speaking. The charge of apathy is one not to be made lightly, but neither is it one to be resented lightly or to be refuted jauntily. That it can be made upon fair grounds is indeed an unpleasant fact in the midst of our luxurious and comfortable civilisation. There must be few in the middle classes and practically none in the upper who could not make a substantial contribution to the hospital treasury. That they do not is due, we think, not so much to want of sympathy as to want of thought. They do not see the sick and wounded. Nurses and hospital surgeons and physicians contend with the worst afflictions—physical, mental, and moral—that can fall upon suffering man every day and all day. But the hospital screens their labours too effectually from the view of those who are in health and comparative wealth and on whom the responsibility of assisting their less fortunate brethren really lies. No doubt amongst these non-subscribing thousands there are many latent Samaritans, but because they do not see the misery of the hospital patients or the beneficent work done for its removal, they allow themselves to fall as part of "the great majority of Londoners," under the charge of apathy. We should gladly welcome conference between those who have done so much for all the hospitals and those who in quieter ways bear the responsibility of individual hospitals, and we should like the results of such coöperation made public, so that those who now pass by on the other side might be moved to give their aid. Apathy in any form, either in those who can give or in those who can administer, is a sin of the first magnitude. There is need for all gleaners in this field. The failure of the voluntary principle to support the London hospitals would be, we consider, a metropolitan disaster and disgrace; it would mean the loss of one of the most binding and healing forces in a huge community which has too many elements of misery and discord.

◆

Tuberculous and Unclean Milk.

There is at the present time a distinct indication that public opinion is awakening from the condition of relative torpor into which it was lulled by the unfortunate statement of Professor Koch in 1901 when he alleged, as the result of a very limited series of experiments, that the danger to the human species from the consumption of tuberculous bovine milk was so small, if it existed at all, that he deemed it unnecessary to take any precautions against it. This expression of opinion, notwithstanding the counterblasts which accompanied it, exercised a distinctly inhibitory effect upon the steps which up to that time were being taken against unwholesome milk in general, there being, strangely enough, after Professor Koch's expression of opinion, an inexplicable tendency to assume that tuberculosis was the only disease which had to be taken into consideration as regards the supply of milk. There can, however, be no longer any doubt that whatever may be the precise degree of danger to be anticipated from the consumption of large numbers of tubercle bacilli in the quantities of milk consumed by children and invalids such danger is a real one, and there are those who believe, as a result of recent experiments, that much of the tuberculosis of adults has its origin in a milk-borne infantile infection which remains latent until, by adverse circumstances of poverty or age proclivity, the human soil becomes so altered as to enable the parasite to grow and to manifest its dire effects. But however this may be, it is possible that the recent experimental work which has shown how easily in certain animals the tubercle bacillus may reach the bronchial glands *viâ* the intestines and the mesenteric glands without leaving in these latter any trace of its passage will render everyone capable of estimating danger disinclined to feed their offspring or even their invalids upon tuberculous milk. It is, therefore, not very reassuring to learn from the reports of Dr. William Collingridge, the medical officer of health of the City of London, that at least 8 per cent. of the milk sold within the City limits is derived from animals affected with tuberculosis. This fact is not, he adds, matter for surprise when it is remembered that out of 500 cows examined, after slaughter, by the city veterinary inspector some evidence of tuberculosis was found in no less than 46·8 per cent. From among 25 samples of milk quite recently examined two were found by Dr. Klein to be tuberculous. As regards the first of these the company to whom the milk was consigned at once discontinued the supply and caused the cows furnishing the milk to be examined by a veterinary surgeon who reported that all, "with the exception of five which have been turned away as showing suspicion of induration which may be tubercular or otherwise," were apparently healthy. In view of this we are glad to be able to record that the company in question arranged for a periodical inspection of the cows. As regards the second sample the veterinary surgeon reported that one cow "is suffering, in my opinion, from tuberculosis of both hind-quarters of the udder." Instances of this nature could be multiplied from the experience of other large towns which have obtained what are known as the Manchester milk clauses but we have said enough to indicate the importance, and indeed the necessity, of the bacteriological examination of milk and the periodical inspection of milch cattle. And altogether apart from tuberculosis there is the very obvious danger to be anticipated from a polluted milk of the conveyance of such diseases as infantile diarrhœa, sore-throat, diphtheria, and scarlet fever, as well as obscure conditions likely to arise from the careless addition of preservatives.

The establishment of numerical bacteriological standards for milk is no doubt a matter of considerable difficulty and we wish at this moment to insist more particularly upon the absolute necessity for cleanliness. In this direction we find ourselves able to derive support from a paper recently read before the Farmers' Club by Mr. F. J. Lloyd, F.C.S., F.I.C., upon the Relation of the Medical Profession to the Dairy Industry. This paper contains certain criticisms of the views of our profession which we do not propose to discuss further than to say that Mr. Lloyd has not thoroughly mastered this portion of his subject. We prefer to devote our space to the points on which we are in agreement rather than to those with which we are out of harmony, since we believe that we shall by this means be best serving the cause which we both clearly have at heart. Mr. Lloyd in the first part of his paper is mainly concerned with an endeavour to prove that what may be termed the bacterial purity of milk is by no means necessary and that the instrumentality of milk in the causation of tuberculosis and infantile diarrhœa has been over-estimated by our profession. We agree, however, with Mr. *Lloyd*, "*that milk to have its maximum value as an article of food must be drunk in a fresh and wholesome condition*," and that consequently "the *dairy farmer* who produces it and all those who have to deal with it should leave no stone unturned which will ensure both its purity and its cleanliness." We are also cordially with Mr. Lloyd in his warning to the dairy farmers that if they wish to prevent extreme legislation they themselves must take the steps to render such legislation unnecessary. From these considerations the writer of the paper goes on to advise the elementary, but little observed, points of cleanliness of the cowsheds, of the cows' udders, and of the milkers' hands, the rejection of the fore-milk, and immediate straining and *cooling of* the milk in thoroughly cleanly circumstances and under conditions where aerial contamination *from* dust is unlikely. To these data he would *doubtless* add by inference facilities for the speedy and *immediate transit* of the milk under conditions which, so far as practicable, will maintain the temperature to which it has been cooled and which will protect it from the dust and dirt associated with a railway journey. As Mr. LLOYD observes: "Even the dairy farmer must realise that the public have a right to demand milk free from disease germs and coming from healthy cows," and he adds that "if the dairy farmer will not take such steps as lie in his power to ensure healthy and clean milk he must not blame the medical profession if in their anxiety to protect the public health they go further than he considers justifiable."

Although Mr. LLOYD believes that the medical profession has already gone further than our present knowledge justifies he is good enough to add that in this country the profession has shown far more moderation than our colleagues in other countries and he trusts that while this moderation continues "the dairy farmer will realise the great responsibility which rests upon him to free his herds from disease and their milk from dirt." We echo these sentiments and we agree with him that it would be well for the dairyman to reckon with us while we are, so to speak, in the gate. We are satisfied with the evidence available that this elementary cleanliness which is so forcibly urged by Mr. LLOYD is not, as a general rule, practised, more especially in our rural districts, where a proposal to wash the udders of the cows and the hands of the milkers prior to the act of milking would often be greeted with derision and where the hind-quarters of the cows are not infrequently caked with filth. The cowsheds are often dark and dirty, the water-supplies far from satisfactory, and the milk utensils unclean. In our own experience the rural inspector of nuisances is all too frequently unacquainted with the Dairies and Cowsheds and Milkshops Order, or the regulations, if any, which have been drawn up under this Order. A much higher standard of cleanliness is desirable in every direction and such standards should be applied with more vigour and consistency. Some intelligent supervision on the part of county councils is, in our view, eminently desirable and we would suggest that Mr. LLOYD should use his influence to promote some such supervision. But it must not be forgotten that the milk as exposed for sale in milkshops and other places is generally kept under conditions which invite its contamination by dust and that much more attention should be devoted to this aspect of the question which is, of course, largely beyond the reach of the dairy farmer.

Cancer Cures.

THERE is an ancient legal maxim, "Ubi jus, ibi remedium," which is usually rendered into English as "There is no wrong without a remedy." We need not stay to inquire whether this aphorism will hold good universally in law. In medicine, unfortunately, the analogous principle that for every disease there is a remedy cannot be maintained at the present time, or if it be true, the remedies for many morbid conditions are utterly unknown to us. Year by year our powers of dealing with disease increase; many maladies which formerly were able to bid defiance to all our therapeutic measures are now almost completely under control. There are, however, unfortunately also many which refuse to be amenable to any form of treatment as yet known to us and probably the most striking member of this group is cancer.

It is now almost universally admitted that malignant disease is local in origin, though some constitutional condition may favour its appearance and spread. When cancer was thought to be "constitutional" in origin its topical removal by surgery was looked upon as impossible, but now that we feel sure that it is local in origin surgery can remove the disease completely if the operation be undertaken before the neighbouring lymphatic glands are involved or dissemination has occurred. At the present time, if the word "cure" can be applied to any procedure in connexion with cancer it can be applied to the early removal of the diseased tissues; but even in this case it is doubtful if "cure" is the most appropriate term to employ, for the diseased tisues have been removed and not restored to a state of health. This, however, is only a question of nomenclature and the fact remains that the early and complete removal of the cancer is at the present time the only satisfactory treatment of the disease. There remain, however, very many cases in which the complete ablation of the diseased tissues is impossible, whether from the original site of the cancer or from the extent of its spread and therefore some other method must be adopted. The attempts to get rid of the morbid growth have been many and every year sees the introduction of new remedies or the resuscitation of some already discarded. Every method is accompanied with a list of cases which have been "cured," but, alas, the results of the trial of the method by others are seldom so favourable as those first attained. Sometimes the new treatment is the outcome of theory. At one time it was imagined that cancer contained an acid and if this were so the obvious treatment would be the use of alkalies. ALLIOT in 1698 said that "the cure of cancer consists in the mollification of acids by alkalies and absorbents." Therefore ammonia was used both internally and externally and much benefit was said to have resulted. VOGEL in 1769 wrote a book called "De Curatione Cancri per Aquam Calcis Vivæ," and the results he described from the use of the lime water were excellent. The effects of chemicals on cancer cells have served to introduce some therapeutic methods. Methyl-violet was at one time used chiefly because it showed an affinity for the cancer cells as seen in sections under the microscope. BROADBENT in 1866 spoke highly of the local injection of acetic acid and the basis of this treatment appears to have been mainly the action of the acid on the cell walls and nuclei of cells on the microscopic slide, and therefore it "might be expected to do this when the cells were *in situ*." His results were certainly striking. It was suggested in 1809 by SAMUEL YOUNG that pressure might lessen the nutrition of a cancer and assist the absorption and several ingenious devices for effecting suitable compression were published. The best known of these was that introduced by NEIL ARNOTT and marvellous "cures" of cancer by these means were described but unfortunately we cannot be certain that the patients were really suffering from cancer. Recently trypsin has been recommended and one of the arguments in favour of its employment is that the secretion of the pancreas probably has a deterrent effect on the production of cancer, since malignant disease is rarely met with between the opening of the pancreatic duct and the ileo-cæcal valve—that is to say, in the part of the bowel where the pancreatic juice is active. As it is still being employed it is yet early to express a definite opinion. Other digestive liquids have, however, been employed long ago; gastric juice is said to have been useful and papain has also been tried.

Narcotic drugs would naturally suggest themselves as useful for allaying the pain but effects which might be called curative have also been described. Storck in 1761 first brought forward conium as a valuable remedy in cancer, though the drug was employed in the disease from a very early date. The drug was widely used and the most diverse opinions have been expressed as to its value. Storck looked upon it as almost infallible but Bayle decided that though it might relieve the pain and retard the progress of the disease it never cured. It is probable that the very great variations which occur in the composition of the preparations of conium may have something to do with the enormous variations in the estimations of its value. Sir Everard Home had a very high opinion of mezereon and at one time belladonna had many advocates. Chian turpentine had an ephemeral reputation some 25 years ago and the failures were ascribed to the use of a false variety of the drug; it was, indeed, difficult to know what was true Chian turpentine but it is wholly disused now. Two or three years ago violet leaves achieved a sudden notoriety from the publication of a remarkable case in which the growth had been examined microscopically and had been declared to be malignant by a competent authority. An infusion of the leaves was used both externally and internally. Other cases have been described in which results equally satisfactory have been obtained and at the present time the infusion of violet leaves is being widely employed but in many cases it does not seem to have had the slightest result. The close nervous association between the genital organs in women and the breasts, as shown by the enlargement of the breasts after childbirth and the involution of the breast which follows the cessation of menstruation, suggested to Dr. G. T. Beatson the possibility of removal of the ovaries controlling the growth of a carcinoma of the breast and a large number of cases has now been recorded, in some of which marked improvement or even disappearance of the tumour has occurred, and as many of the cases were instances of inoperable recurrent growths, in which there had been a microscopic examination of the primary tumour, the value of the observations is great but the more carefully the cases are investigated the smaller is the proportion in which improvement has occurred. Cancer has been ascribed both to too much salt and also to too little salt in the diet; nevertheless, the injection of sodium chloride has been said to do good. Of external remedies the number is great. We need say little of real caustics, such as arsenic, for if sufficient tissue is destroyed the disease may be removed; but belladonna, lead, mercury, and iodine seem to have had the greatest reputation. Substances so inert as silica and animal charcoal have been declared to be capable of "curing" cancer. Toads have been applied externally and many other remedies as strange have been highly recommended. In 1781 a Mexican physician, Florès, advised the administration of the flesh of the grey lizard but Bayle had a patient who swallowed more than 400 grey lizards within two months and yet received no benefit. In these latter days light rays and x rays have been shown to have a very decided curative action on the superficial forms of carcinoma, such as rodent ulcer, and it is now well established that these varieties of malignant disease are curable by such means. It is of interest to note that in 1776 Le Comte employed the rays of the sun concentrated by a lens in the treatment of a cancer of the lower lip and the growth is said to have disappeared. The value of "serums" in various diseases naturally suggested the attempt to prepare an "anticancerous serum." Doyen described a bacillus neoformans and from it prepared an anticancerous serum, from the use of which he obtained definite improvement but other observers have failed to get satisfactory results. In THE LANCET of April 7th (p. 955) Dr. A. Paine and Dr. D. J. Morgan described their observations on a series of cases in which Doyen's serum was employed but in no case was any benefit seen. Dr. O. Jacobs and Dr. Victor Geets of Brussels in the same issue of THE LANCET (p. 964) published a paper in which, while agreeing that Doyen's serum was valueless, they maintain that "it is practicable to immunise the human organism by means of a series of inoculations of the micrococcus neoformans vaccine provided that these are properly controlled by examinations of the opsonic power of the blood." We acknowledge the importance of this communication and await with interest the results of a further trial of the method.

In giving this brief review of the treatment of cancer we have omitted many drugs employed at one time or another but we have mentioned enough to show that many substances have been brought forward from time to time as curative of cancer and often detailed accounts have been given of the progress and improvement of the cases and yet in other hands the treatment has proved useless. To what are we to ascribe this apparent inconsistency? The chief explanation is to be found in errors of diagnosis. Even now, when we possess many aids to diagnosis which our predecessors did not have, errors as to the nature of a tumour are by no means rare. They must have been very common in the past. A chronic mastitis of the breast may be indistinguishable from carcinoma until cut into or even until a section has been examined microscopically. We can hardly imagine that pressure could cause the absorption of a true scirrhus of the breast and we are forced to believe that the cases in which the use of Arnott's pads was followed by disappearance of the tumour were in reality cases of chronic inflammation of the breast. Another factor in the production of the curious history of cancer cures is the irregularity of the course of cancer. Though as a rule a malignant growth steadily progresses to a fatal issue, cases are seen in which the diagnosis has been indisputable and confirmed by microscopic examination, yet for some unknown reason the extension of growth ceases, to be replaced by atrophy, and sometimes even the whole mass may disappear. This has occurred even when no treatment has been employed. If, however, there has been administered any drug at the time when the growth has diminished that drug will surely get the credit of the improvement and in this way the reputations of many drugs have been made. We must from a careful consideration of all the facts be led to the conclusion that in the vast majority of recorded cases where malignant growths have been said to be cured the growth was not cancerous, but we must express our dissent from the view maintained by some that the disease in all such cases was not really malignant because it was "cured." We have hope in the future. The discovery by Professor JENSEN of an inoculable form of malignant disease in mice has made it easy now for us to try the effects of remedies in a way which was impossible when we were limited to cases occurring in human beings. We think that by this discovery Professor JENSEN has done much to further the advance of the study of cancer and we heartily approve of the action of the Royal College of Surgeons of England in according to him the Walker prize. Not merely, however, in the cure of cancer when it exists but in the prevention of the disease the greatest future advance will lie.

Annotations.

"Ne quid nimis."

THE METROPOLITAN WATER BOARD AND THE CONTAMINATION OF THE RIVER LEA.

THERE has been considerable speculation amongst water experts during the week as to the reasons which have led the Metropolitan Water Board to drop its Bill providing for the better protection of the water-supply drawn from the river Lea. It would appear that the Water Board contemplated in its Bill the removal of one of its intakes from the Lea to a point higher up the river, a step which seemed highly desirable owing to the increasing volume of sewage which was poured into the river from the town of Hertford above the old intake. The supply of water taken from the river below the sewage outfall amounts, it is stated, to 32,000,000 gallons per day, while the Hertford sewer discharges about 2,000,000 gallons of crude sewage per day into the river above this point. These figures and statements if true are not calculated to inspire the confidence of the consumers living in the Eastern districts of the metropolis in the quality of the water supplied to them. On the contrary, a feeling of alarm may very justifiably arise, especially as it is common knowledge that the Metropolitan Water Board must have realised the seriousness of the situation or it would not have promoted a Bill dealing with it. The alarm is not likely to subside now that it is announced that the Lea Valley Bill has been withdrawn. We understand that the subject will be discussed at the next meeting of the Board and it is to be hoped that the reasons given for the withdrawal of the Bill will be reassuring to the public. Meantime it is conjectured that an alternate scheme has been proposed which possibly provides for the diversion of the stream of sewage discharged from the Hertford sewer. It is also stated that the Water Board is seriously considering the scheme promoted some years ago by the London County Council for obtaining a supplementary supply of water for London from the Welsh hills. But obviously such a scheme cannot meet the immediate needs of the situation as regards the alleged pollution of the river Lea above the Water Board's intakes. We may point out that this source of pollution of the water-supply derived from the Lea by the old East London Waterworks Company was referred to in the articles on the London water-supply which appeared in *THE LANCET* in 1897; the state of the sewage effluent is described there as varying considerably. Sir Alexander Binnie has given it as his opinion that a time would come, if the present state of things continues, "when there will arise among the teeming millions of London an epidemic which will startle the world" and compared with which the scope of previous outbreaks of water-borne epidemics will pale into insignificance. These are very strong words and seem to us to warrant a very searching inquiry into the real facts of the case. We have again and again pointed out that though the actual volume of the water provided by the Thames and the Lea may meet the existing needs of the metropolis for drinking purposes it must not be forgotten that year by year the strain put upon these rivers as channels for the disposal of sewage effluents is increased and the risk of pollution consequently is greater.

THE PLACE OF CRIMINOLOGY IN THE CURRICULUM OF LEGAL EDUCATION.

THE conflict between medical and legal opinion with regard to the criminal responsibility of the insane, which a few years ago was wont to give rise to so much acute and often acrimonious controversy in the Courts of Justice, has in our days ended in what may not unfairly be claimed as a full though tacit acceptance of the views of medical science. The crude psychology which inspired the M'Naughten rules, if it has not been explicitly repudiated, has at all events been abandoned in practice; and in criminal cases nowadays there is little fear that expert evidence of the fact of mental disease will be discounted on the score of any obsolete test of responsibility. But while this change of attitude is very satisfactory so far as it goes, it would certainly be rather rash to assume that it is the result of any profound knowledge and appreciation of the teachings of modern psychiatry and that the legal mind is so well informed on all that relates to the scientific study of the criminal that it will be able to give an unprejudiced consideration to the practical suggestions which may be founded on that study in the near future. It is to be feared that this permeation of the law by the modern spirit is still an ideal the realisation of which is somewhat remote and only attainable through strenuous efforts in which the medical profession must zealously coöperate. On this account peculiar interest attaches to the noteworthy example recently set us by our Gallic neighbours who have formally introduced the study of criminology into the curriculum of legal education. By a decree of the Council of the University a course of instruction in criminal anthropology, mental diseases, legal medicine, and cognate subjects has been instituted in the Paris Faculty of Law. The course will extend over two terms and will comprise lectures delivered by the professors in the faculties of law and medicine, supplemented by clinical instruction. Attendance on the course will be recognised, after the usual examination tests, by the granting of a *certificat d'études de sciences pénales*. In view of the generally hostile attitude hitherto adopted by the French magistracy to the ideas of the criminologists this step is of very great significance. Nor, it may be remarked, is the tendency which it indicates confined to France. In the University of Berlin a series of lectures on criminal anthropology has just been inaugurated and, though not in any formal connexion with the faculty of law, must exercise a considerable influence on legal opinion. Of course, the method of procedure in criminal cases in France, which demands of the *juge d'instruction* a good deal of insight into the criminal temperament, makes the need of such a system of training more apparent than it is in England. Such differences, however, as arise from this cause are relatively slight and superficial and do not affect the fundamental factors of the question, which are essentially the same in all civilised countries. It is, therefore, to be hoped that when the long-talked-of reorganisation of legal education in England eventually takes place something on the same lines will be established here and that it will be recognised as absurd that men should be called upon to judge of the quality and motive of diseased conduct who have never been trained to the study of morbid thought and action in the wards of the prison and the lunatic asylum. It is not to be denied, however, that in this country, at all events, there exists a feeling among those who have had practical and personal experience among criminals that there is some risk of overdoing "criminology" as a subject of education. This risk attaches more especially to the application of general results to individual criminals, but the question is one which it is desirable to follow out in the hope that lawyers and medical men may be able to bring their divergent opinions into greater harmony with each other.

THE TREATMENT OF RECOVERABLE CASES OF INSANITY.

In the management of cases of mental disorder in which the prospects of recovery are favourable the general practice would probably be correctly described as based upon the principle of as little interference as possible, incidental symptoms only, such as insomnia, violence, and refusal of food, being treated. The general practice may, in fact, be compared to that adopted in the case of maladies such as the specific fevers which must be allowed to run their course. On the other hand, there are not wanting those who advocate and employ methods which aim directly at cure. The relative merits of "expectant" and active methods of dealing with the cases in question are capable of demonstration by means of a comparative trial. In a pamphlet which we have received and which is entitled "A Plea for the more Energetic Treatment of the Insane" the author, Mr. Charles Williams, whilst disclaiming any desire to reflect upon asylum physicians, nevertheless considers that they as a class are deficient in the quality of zeal. There are, he contends, various methods by which at any rate some small addition to the recovery-rate of asylums might be made but this does not appear to be considered worth having. Amongst the methods instanced are the treatment by thyroid extract, electrical treatment in various forms, the prolonged warm bath, the Turkish bath, suggestion and the production of some somatic disorder which would favourably influence the course of the mental disease. Some of these methods lend themselves to adverse criticism. There are others which, whilst not mentioned in this pamphlet, are in good repute. A perusal of modern treatises upon insanity in which we find advocated various methods calculated to bring about cure or to hasten recovery in recoverable states does not support the view that recoverable cases are best left to nature and the nurse, though the convincing proof which a comparative trial of the kind we have suggested would afford is not furnished. Such a study, however, may well raise a doubt as to whether the average conditions under which the work of our public asylums is done are likely to foster that zeal which is the basis of all achievement or are compatible with the prosecution of research, the elaboration of methods of treatment, and the application of these with thoroughness in individual cases. The erection of "acute hospitals" for the treatment of recent and hopeful cases in certain rare instances at public asylums is evidence that such a doubt is legitimate. But whilst the motive which actuates such a development in a county asylum is admirable and the plan itself an advance on the average conditions, the asylum is still an isolated community and subject to the disadvantages in respect of scientific progress which isolation in no small degree connotes. The opinion is, and has for some time been, held by many able workers in the department of psychological medicine that such progress is most likely to accrue from the association of wards for mental cases with ordinary hospitals wards, an arrangement by which it is contended that collaboration would be facilitated and the advantage of laboratories for various branches of research work insured to the worker in the special department; whilst his activities would be stimulated by the presence of students and his output largely increased by the assistance of zealous clinical clerks working under his directions.

THE CLOTHES BRUSH.

The brushing of dusty clothes in the living rooms of the household is opposed to cleanly sentiment, apart altogether from the evil to health which, as the bacteriology of dust distinctly indicates, might easily be caused by the process. The imagination does not require to be stretched very far to realise that the clothes brush might be easily responsible for the dissemination of disease. Dust is rarely, if ever, free from micro-organisms and amongst them pathogenic entities have been recognised. Dust is, in fact, an enemy of the human race, a vehicle of disease, and should everywhere and on every occasion, however trifling, be prevented as far as means can be employed to that end. The clothes brush is a vigorous dust-producing agent and since its application is indispensable it should be used in a manner as far as possible consistent with hygienic requirements. Clothes, of course, must be brushed just as carpets must be beaten but both processes create a nuisance which is different not in kind but only in degree. Just, therefore, as there are grounds reserved for the beating of carpets remote, as they should be, from human habitation, so also ought there to be in a household conducted on hygienic lines a special room relegated to the brushing of clothes. Enthusiastic sanitary reformers would, no doubt, suggest that provision might also be made for trapping the dust by some such simple measure as suspending a damp sheet across the room. The daily clothes have a large capacity and a singular affinity for dust which may contain the seeds of a common cold or a sore-throat or even of blood poisoning and tetanus, so that the suggestion that the clothes brush should be handled in a less indiscriminate way than is usually the case can hardly be regarded as chimerical. If dust has been proved to be pathogenic the scattering of it broadcast by means of the clothes brush must be a violation of hygienic principles. The brushing of clothes is, in fact, a clumsy and an insanitary procedure which might with advantage be superseded by some more effectual and less offensive method. The use of some kind of vacuum brush for the purpose would, sanitarily speaking, be ideal.

SOME RECENT ADDITIONS TO THE MATERIA MEDICA.

The *Journal de Pharmacie et de Chemie* gives particulars of two new preparations of iodine which may prove of therapeutic value. It has been suggested by M. Chassevant that chloroform has advantages over alcohol as a solvent of iodine. The 10 per cent. solution when applied to the skin causes a brown stain which is less persistent than that produced by tincture of iodine. It does not cause desquamation, even in concentrated solution, or itching, or dermatitis, as is so often the case with alcoholic preparations of iodine. When applied in this manner iodine is readily absorbed and may be detected in the urine ten minutes after the solution has been applied. It is thought that iodine exists in solution in different allotropic forms, the chloroformic solution being violet in colour and the alcoholic solution brown. M. Chassevant considers the chloroformic solution to be the most suitable preparation for the internal administration of the drug. A new preparation of iodine for internal use has been devised by M. Vaudin. It is prepared by treating maisine, an albuminoid principle contained in the gluten of maize, with iodine. The product, iodomaisine, is a yellowish, hygroscopic substance, soluble in water and having a bitter taste. In daily doses of from 10 to 12 centigrammes it is easily tolerated by the stomach and has given beneficial results in emphysema, tertiary syphilis, and in other cases where the internal administration of iodine was indicated. The composition and uses of several new medicinal substances have been described in a recent number of the *Bulletin des Sciences Pharmacologiques*, including apocodeine hydrochloride, palladium chloride, aldol, malonal, and salene. Apocodeine hydrochloride is a yellowish powder, soluble in water, and is given as a laxative in place of codeine phosphate. It may be administered in doses of two cubic centimetres of a 3 per cent. solution. Palladium chloride, a brownish-black substance, soluble in water, is given in pulmonary tuberculosis in doses of from five to ten drops of a 3 per cent. solution. Aldol, an aldehyde alcohol, is a colourless liquid with an agreeable taste and a characteristic odour. It has been employed as a hypnotic. Malonal (diethyl-malonyl-urea) has been introduced for the same purpose. Salene is the name given to a mixture of the ethylic and methylic esters of salicyl-acetic acid. It occurs in white, odourless crystals, soluble in alcohol and in a mixture of olive oil and chloroform. It is used as a liniment in cases of lumbago and acute or chronic rheumatism, the solution being rubbed on the painful parts two or three times a day.

THE HEROISM OF THE MAN OF SCIENCE.

IF "*Peace hath her victories*" she has also her heroes, and the same may be said of science—never more impressively than in the day now passing. The Roman legionary who was found dead at the sea-gate in the Pompeii of A.D. 79, "waiting for orders to leave," has had his counterpart in the director of the Osservatorio Vesuviano, Dr. Vittorio Raffaele Matteucci who, when the recent eruption was at its worst and the whole countryside had fled in panic, remained on duty taking his observations and carefully registering them in the interests of science and, in the last resort, *pro bono publico*. Fortunately his life has been spared though not without physical lesion and his report of a volcanic convulsion, in some respects unprecedented, will shortly be available for his fellow workers in the same field of nature study. Heir to an honoured name in electro-biology, he was born 46 years ago at Sinigallia on the Adriatic and graduated at the University of Naples "in studiis naturalibus," subsequently devoting himself specially to "petrografia" and "vulcanologia" at the University of Heidelberg. On his return to Italy he entered immediately on investigations into the "osservazioni Vesuviane" which were to be his life-long task, fearlessly approaching the crater in its angriest moods and once, indeed, so injured in the knee by a "bomba volcanico" that he was lame for a considerable time. When four years ago he succeeded to the post of "Direttore dell' Osservatorio Vesuviano' and took up his abode on the ridge of the mountain, he showed himself worthy of his great predecessor, Professor Palmieri, whose work went on unperturbed amid showers of pebbles and ashes till on one occasion every pane of glass was broken in the Observatory which rocked to its foundations. Fortunate, like Palmieri, in his assistants Dr. Matteucci has for three years been ably and intrepidly reinforced by Dr. Di Paola, his right-hand man, by Dr. Cassorio, the next in command, and by the chaplain, Don Saverio Formisano, who, with four serving-men, complete the working staff. He also holds a lectureship in the University of Naples and enlists so many enthusiastic students in his special subject as to encourage the hope that seismology, still in its infancy, may before the century is much older give up its secrets to the researches now proceeding apace in the many volcanic or earthquake-visited regions of the old and the new worlds.

CHARING CROSS HOSPITAL POST-GRADUATE LECTURES.

POST-GRADUATE lectures dealing with general medicine and surgery have been given at Charing Cross Hospital for some 15 years. The lectures have been delivered on Thursdays only but the authorities have now decided to add Mondays as days for the delivery of lectures on special subjects. The summer course of the current year will commence on Monday, April 30th, with a lecture by Dr. James Galloway on a dermatological subject. On Thursday, May 3rd, Dr. H. Montagu Murray will lecture on a medical subject. The lectures will commence at 4 P.M. and will continue on Mondays and Thursdays from April 30th to July 5th inclusive. The full programme will be found in our advertisement columns of this week and a notice of the lectures will appear week by week in the "Diary." The fee for the full course is two guineas, or for either day singly one guinea. Practitioners wishing to join the course should communicate with the Honorary Secretary, Post-graduate Course, Charing Cross Hospital.

HÆMOPHILIA IN THE NEWLY BORN.

IN the *American Journal of the Medical Sciences* for March Dr. R. C. Larrabee has published an important article on the rare condition of hæmophilia in the newly born. Uncontrollable hæmorrhage in the newly born is seldom due to hæmophilia and appears to be generally due to some infection. Many organisms have been found at necropsies or in the blood during life. These include staphylococci, the streptococcus, the pneumococcus, bacillus pyocyaneus, the bacillus lactis aerogenes, and the bacillus coli. The course of the disease resembles that of an acute infectious disease and outbreaks have occurred in hospitals. So much attention has been lately given to the infectious origin of hæmorrhage in the newly born that the possibility of its being due to hæmophilia has been to a certain extent overlooked. Some writers have even denied that hæmophilia ever occurs in the first few days of life. No doubt it generally begins in later childhood but there are exceptions. In 1872 Grandidier collected 228 cases of spontaneous umbilical hæmorrhage and of these 14, or 6 per cent., occurred in hæmophilic families. Dr. Larrabee has been able to collect 37 cases of hæmophilia in the newly born. These include one observed by himself as well as those collected by Grandidier. No case was accepted as one of hæmophilia unless there was a family history of the disease or unless the child survived and in later life was a "bleeder." The 37 cases occurred in 24 families. 22 of the cases were fatal—a mortality of 60 per cent. The sex incidence was according to the rule in hæmophilia: out of 33 cases only six patients were females. On the other hand, in the cases in which the hæmorrhage was due to infection the sexes were about equally divided. The most common site of the hæmorrhage was the umbilicus or umbilical cord (23 cases, in 19 of which this was the only site). Other sites were the skin (seven cases), the nose (six cases), the bowel (four cases), the joints and genito-urinary tract (two cases each), an operation wound, the gums, and the stomach (one case each). In two cases the site was not stated. Although several writers state that circumcision is often the cause of the first hæmorrhage Dr. Larrabee has been able to find only one undoubted case. His own case is exceptional as regards sex and the manner of transmission. A girl was born at term after a normal labour. The membranes were ruptured artificially and in doing this a minute scratch was made on the child's head. The hæmorrhage from this was never controlled. The child weighed 5 pounds and was apparently normal. The cord was tied in the usual way but after a few hours slight hæmorrhage occurred from the cut end. This continued irregularly in spite of several ligatures. On the second day epistaxis occurred and then hæmorrhage from the rectum, the stools being large and black with some bright red blood. On the same day purple spots began to appear, first on the face. Blood came from under the finger nails and even appeared to ooze from the unbroken skin. Prostration was marked and the temperature was constantly subnormal. On the fifth day there was a copious hæmorrhage from the vagina and death soon followed. There was a family history of hæmophilia for five generations. In the first generation an ancestor of the patient emigrated from England to America in 1757; there was a tradition that his brother bled to death. He had three sons and one daughter, none of whom were "bleeders," but in the succeeding generations there were 22 cases of hæmophilia, of which 11 were fatal. However, many of these cases were merely traditional. The transmission was not according to the usual rule. Out of 15 known and well-marked cases the disease was inherited through the male in 10. Possibly this preponderance was more apparent than real, because information concerning the descendants of female members of the family was defective Genealogies in the female line are neglected because they are not considered of much interest. It is important to bear in mind that hæmorrhage in the newly born is generally due to some infection and not to hæmophilia.

IDEALS.

WE have received a little pamphlet bearing the heading of "Literature and Us" and consisting of two papers originally published in the *St. Bartholomew's Hospital Journal* in December, 1905, and March, 1906.[1] The "Country G. P." who is the writer of the papers is evidently a man of wide reading and of cultured tastes, two qualities which are, above all, desirable for a medical man who is as much as, if not more than, any minister of religion brought daily into contact with the naked souls of his fellow men. For any man who can rightly appreciate the thoughts, as expressed in their writings, of profound thinkers must necessarily be able better to aid those who seek him in affliction, either of body or mind, and the two are practically indissoluble, than one who is on a lower plane of thought. So we have read with great interest the "Country G.P.'s" two papers, in the first of which he gives us quotations with comments from the writings of great and good men who have dealt with the medical profession, its duties, its hardships, and its rewards. In the second paper, "Some Ideals of a Doctor," he gives us his ideal of what a medical man should be, an ideal which he confesses he has not by any means reached himself. But to have an ideal is to take the first step towards acquiring the same and all of us may find ourselves better from reading the main points of the ideal set up in this paper. Thus the ideal medical practitioner should have some definite notion in his mind of what he is going to do for his patient; he should remember that "Res est sacra miser"; he should bear in mind the aphorism—

> "Aequam memento rebus in arduis
> Servare mentem";

and should always recollect that "Him whom you have not saved while you might, that same have you killed." He should not be idle, should be temperate and tactful in all things, and when death comes to his patient he should, and often can, stay the sorrowing who are left behind, with the consolation that death is not the end. He gives various quotations upon this point and we would suggest that he should add Blanco White's magnificent and single sonnet, "Night and Death," to his list. We see that he promises a third paper—namely, "What We must Live Down"—and we look forward to this with much interest.

UNILATERAL SENSORY DISTURBANCE LIMITED TO ONE LIMB AND WITHOUT MOTOR PARALYSIS SUBSEQUENT TO HEAD INJURY.

Dr. William G. Spiller records in the *Journal of Nervous and Mental Disease* for February, 1906, a case which may be added to collected instances of disorder of sensation, sometimes amounting to hemianæsthesia and without motor paralysis resulting from a lesion of the cortex cerebri. The patient, a male, aged 38 years, was struck with a club over the region of the right parietal lobe. He was unconscious for an hour or two and for the next two weeks was unable to move the fingers of the left hand It was not possible to say whether this inability was the result of motor weakness or of sensory disturbances. The left leg could be moved on the day following the injury and did not at any time exhibit disorders of sensation or of motion. His condition when examined nearly 18 months after the injury was as follows. Whilst there was no weakness of the left upper limb its movements were awkward; with the eyes closed he could not button his coat with the left hand; the sense of position was greatly impaired in the left fingers, as also was stereognostic perception in the left hand, so that he usually failed to name an object placed in it unless he used the sense of sight. Sensations of touch, pain, and temperature were diminished in the left hand, though to a less degree than the above. Sensation was unaffected on the left side of the face and chest and in the left lower limb. This case is further of interest as showing that disorders of sensation in connexion with cerebral cortical lesions may be confined to one limb and therefore affords evidence in favour of the belief that the area for common sensation, like the motor area, is divisible into different centres.

THE DEATH OF M. PIERRE CURIE.

THE death of M. Curie in a street accident in Paris brings to a terribly sudden end the very brilliant career of a scientific man gifted with a remarkable capacity for original research. M. Curie was only 47 years of age, so that there seemed to be abundant opportunities still ahead of him for further applying his sagacity and energies to great scientific questions, and above all, to the mystery of the nature of things, the composition and constitution of matter, and the problem of energy. Fate decreed otherwise and his life was cut short by a prosaic accident in the street. He fell under a heavily loaded wagon and was killed instantly, the wheels passing over his neck. M. Curie's death is a terrible loss to the world of science which, it is not disparaging to others to say, could spare him least amongst its faithful followers. He enjoyed a singularly happy partnership with his wife, for she devoted herself to her husband's life work, with what great and far-reaching results the whole world knows. Madame Curie was the actual discoverer of radium and its analogues but her long, patient, and laborious investigations had the advantage of being directed by her husband. Intense sympathy will be felt for Madame Curie who has thus so suddenly lost not only her husband but a fellow worker in a companionship which gave to the world one of the most remarkable discoveries in the history of science, if not the most remarkable. What a new and immense field of exploration, with the promise of great possibilities, have the joint brilliant researches of M. and Madame Curie opened up. The discovery of radium did indeed revolutionise scientific ideas. One of the discoverers has now been snatched away by death but his marvellous work remains, and M. Curie's name will receive homage and veneration "from one generation to another."

PLUMBISM FROM THE ADMINISTRATION OF ACETATE OF LEAD IN MEDICINAL DOSES.

IN *American Medicine* of March 31st Dr. William Pepper has reported a case of plumbism due to an unusual cause—the administration of lead in medicinal doses. A teamster, aged 53 years, was admitted into hospital on August 28th, 1905, for chronic diarrhœa. He complained of pain in the abdomen and tenesmus. The abdomen was tense and rigid but not tender. There was a marked blue line on the gums. The urine contained a little albumin and a few granular and numerous hyaline casts. For a few days the abdominal pain was severe. After admission there was no diarrhœa and in spite of the administration of magnesium sulphate there was only one stool daily. On Sept. 15th the abdominal pain had disappeared. The patient had never handled lead or paint or, so far as could be ascertained, come into contact with lead in any form, but during the summer he had taken for diarrhœa one-grain doses of acetate of lead which was prescribed in the form of a mixture. The exact amount of lead taken could not be ascertained, but as he suffered during the summer months from severe diarrhœa with an average of about ten stools daily it was estimated that he took several drachms of acetate of lead. A similar case was previously recorded in *American Medicine* of Oct. 14th, 1905, by Dr. Arneill. In a case of dysentery he prescribed acetate of lead. It was thought that the patient took from two to two and a half drachms of acetate of lead in five or six weeks. He had a typical blue line on the gums and suffered intensely from colic, which was relieved after ten days' treatment. These cases show the necessity of caution in prescribing lead for any length of time.

THE STERILISATION OF CATGUT.

IN an article which was published in a recent issue of the *Archives de Médecine et de Pharmacie Militaires* Surgeon-Major J. Tanton describes an inexpensive and easily carried out process which he has devised for rendering catgut permanently sterile without in the least impairing its surgical efficiency. The numberless methods suggested for sterilising ligatures which come to light every day show plainly, he says, that this question, so important to the practising surgeon, has not as yet received final elucidation. It would take up too much space, he adds, to give a complete list of these methods, and, moreover, no good purpose would be served thereby, inasmuch as the great majority of them has been abandoned. A few are left that give excellent results, but of these some are proprietary, whilst others of which the mode of preparation has been made public require special and elaborate apparatus for their production and are therefore unsuitable for small hospitals which for the most part do not possess either an autoclave or a Pasteur stove. Having on several occasions experienced disappointment when trusting to the catgut supplied from departmental sources Surgeon-Major Tanton was led to investigate the manufacture of the article and accordingly instituted a series of experiments which occupied him for more than a year. The problem at issue was the production by some simple and inexpensive process of surgical catgut whereof the sterility would be absolute, while at the same time its strength and flexibility were fully maintained. The finished article produced under these conditions was tested for upwards of a year in a military hospital in Algeria and also by a brother officer of the inventor, Surgeon-Major Folly of Koléah, the results in both cases being highly satisfactory. Surgeon-Major Tanton's method of procedure is as follows, the sterilising agent finally selected by him being iodine dissolved in acetone. The catgut of commerce must first be completely denuded of grease. To effect this the operator begins by rubbing it briskly with a pad of absorbent cotton-wool that has been steeped in ligroine. He next rolls it loosely in a single layer round small glass rods or tubes and places these in a flask of ligroine where he leaves them for about 20 days. The rods are then taken out and exposed to the air for about 24 hours or until the ligroine has evaporated. They are then placed in a 2 per cent. solution of iodo-acetone contained in a wide mouthed yellow flask (previously sterilised by means of boiling water) which must be kept hermetically closed. After standing for a month in a dark place the rolls of catgut are transferred with sterilised pincers to a flask of 90° alcohol for storage until required. When first taken out of the iodo-acetone the catgut is hard and somewhat brittle but the spirit soon removes the excess of iodine left by the evaporation of the acetone and restores flexibility. In order to test the sterility of the iodo-acetonised catgut specimens were soiled with various cultures, including staphylococcus aureus, streptococcus pyogenes, the bacillus of Yersin, bacillus subtilis, and bacillus mesentericus, and in every case sterility was perfectly maintained. Even when trampled under foot the ligatures did not lose their neutrality. Iodo-acetone vapour irritates the conjunctiva and causes excessive lacrymation but this defect is removed by the alcohol.

A TELEGRAM from the Governor of Hong-Kong received at the Colonial Office on April 18th states that for the week ending April 14th there were 21 cases of plague and 23 deaths from the disease. For the week ending April 21st there were 44 cases and 37 deaths. At Brisbane the official bulletin of the Department of Public Health, Queensland, states that for the week ending March 17th no case of plague was notified, the last case notified having occurred on March 6th.

THE King has granted to Mr. Reginald Gower Kirton, M.D. Lond., principal medical officer of the Egyptian Prisons Administration, His Majesty's Royal authority to wear the Insignia of the Fourth Class of the Imperial Ottoman Order of the Osmanieh, which decoration has been conferred upon him by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey, in recognition of valuable services rendered by him.

THE King has been graciously pleased to sanction the following appointments to the Order of the Hospital of St. John of Jerusalem in England:—To be Knights of Grace: John Samuel Griffiths, M.R.C.S. Eng., L.R.C.P. Lond., Ernest Laurie Robinson, M.R.C.S. Eng., L.R.C.P. Lond., Surgeon-Lieutenant-Colonel Frederick William Gibbon, V.D.; and Surgeon-Lieutenant-Colonel Edward Cureton, V.D.

THE President of the Local Government Board, accompanied by his private secretary and Dr E. J. Steegmann, secretary to the Royal Commission on Tuberculosis, visited on Friday the farms and laboratories at Stansted, Essex, where the research work of the Royal Commission is being carried on, with the generous coöperation of the proprietor, Sir James Blyth.

THE festival dinner of the City of London Hospital for Diseases of the Chest will be held at the Trocadéro Restaurant, Piccadilly-circus, London, on Friday, May 11th, artificially and in doing this a minute scratch was made on the child's head. The hæmorrhage from this was never controlled. The child weighed 5 pounds and was apparently normal. The cord was tied in the usual way but after a few hours slight hæmorrhage occurred from the cut end. This continued irregularly in spite of several ligatures. On the second day epistaxis occurred and then hæmorrhage from the rectum, the stools being large and black with some bright red blood. On the same day purple spots began to appear, first on the face. Blood came from under the finger nails and even appeared to ooze from the unbroken skin. Prostration was marked and the temperature was constantly subnormal. On the fifth day there was a copious hæmorrhage from the vagina and death soon followed. There was a family history of hæmophilia for five generations. In the first generation an ancestor of the patient emigrated from England to America in 1757; there was a tradition that his brother bled to death. He had three sons and one daughter, none of whom were "bleeders," but in the succeeding generations there were 22 cases of hæmophilia, of which 11 were fatal. However, many of these cases were merely traditional. The transmission was not according to the usual rule. Out of 15 known and well-marked cases the disease was inherited through the male in 10. Possibly this preponderance was more apparent than real, because information concerning the descendants of female members of the family was defective Genealogies in the female line are neglected because they are not considered of much interest. It is important to bear in mind that hæmorrhage in the newly born is generally due to some infection and not to hæmophilia.

IDEALS.

WE have received a little pamphlet bearing the heading of "Literature and Us" and consisting of two papers originally published in the *St. Bartholomew's Hospital Journal* in December, 1905, and March, 1906.[1] The "Country G. P." who is the writer of the papers is evidently a man of wide reading and of cultured tastes, two qualities which are, above all, desirable for a medical man who is as much as, if not more than, any minister of religion brought daily into contact with the naked souls of his fellow men. For any man who can rightly appreciate the thoughts, as expressed in their writings, of profound thinkers must necessarily be able better to aid those who seek him in affliction, either of body or mind, and the two are practically indissoluble, than one who is on a lower plane of thought. So we have read with great interest the "Country G.P.'s" two papers, in the first of which he gives us quotations with comments from the writings of great and good men who have dealt with the medical profession, its duties, its hardships, and its rewards. In the second paper, "Some Ideals of a Doctor," he gives us his ideal of what a medical man should be, an ideal which he confesses he has not by any means reached himself. But to have an ideal is to take the first step towards acquiring the same and all of us may find ourselves better from reading the main points of the ideal set up in this paper. Thus the ideal medical practitioner should have some definite notion in his mind of what he is going to do for his patient; he should remember that "Res est sacra miser"; he should bear in mind the aphorism—

PLUMBISM FROM THE ADMINISTRATION OF ACETATE OF LEAD IN MEDICINAL DOSES.

IN *American Medicine* of March 31st Dr. William Pepper has reported a case of plumbism due to an unusual cause—the administration of lead in medicinal doses. A teamster, aged 53 years, was admitted into hospital on August 28th, 1905, for chronic diarrhœa. He complained of pain in the abdomen and tenesmus. The abdomen was tense and rigid but not tender. There was a marked blue line on the gums. The urine contained a little albumin and a few granular and numerous hyaline casts. For a few days the abdominal pain was severe. After admission there was no diarrhœa and in spite of the administration of magnesium sulphate there was only one stool daily. On Sept. 15th the abdominal pain had disappeared. The patient had never handled lead or paint or, so far as could be ascertained, come into contact with lead in any form, but during the summer he had taken for diarrhœa one-grain doses of acetate of lead which was prescribed in the form of a mixture. The exact amount of lead taken could not be ascertained, but as he suffered during the summer months from severe diarrhœa with an average of about ten stools daily it was estimated that he took several drachms of acetate of lead. A similar case was previously recorded in *American Medicine* of Oct. 14th, 1905, by Dr. Arneill. In a case of dysentery he prescribed acetate of lead. It was thought that the patient took from two to two and a half drachms of acetate of lead in five or six weeks. He had a typical blue line on the gums and suffered intensely from colic, which was relieved after ten days' treatment. These cases show the necessity of caution in prescribing lead for any length of time.

THE STERILISATION OF CATGUT.

IN an article which was published in a recent issue of the *Archives de Médecine et de Pharmacie Militaires* Surgeon-Major J. Tanton describes an inexpensive and easily carried out process which he has devised for rendering catgut permanently sterile without in the least impairing its surgical efficiency. The numberless methods suggested for sterilising ligatures which come to light every day show plainly, he says, that this question, so important to the practising surgeon, has not as yet received final elucidation. It would take up too much space, he adds, to give a complete list of these methods, and, moreover, no good purpose would be served thereby, inasmuch as the great majority of them has been abandoned. A few are left that give excellent results, but of these some are proprietary, whilst others of which the mode of preparation has been made public require special and elaborate apparatus for their production and are therefore unsuitable for small hospitals which for the most part do not possess either an autoclave or a Pasteur stove. Having on several occasions experienced disappointment when trusting to the catgut supplied from departmental sources Surgeon-Major Tanton was led to investigate the manufacture of the article and accordingly instituted a series of experiments which occupied him for more than a year. The problem at issue was the production by some simple and inexpensive process of surgical catgut whereof the sterility would be absolute, while at the same time its strength and flexibility were fully maintained. The finished article produced under these conditions was tested for upwards of a year in a military hospital in Algeria and also by a brother officer of the inventor, Surgeon-Major Folly of Koléah, the results in both cases being highly satisfactory. Surgeon-Major Tanton's method of procedure is as follows, the sterilising agent finally selected by him being iodine dissolved in acetone. The catgut of commerce must first be completely denuded of grease. To effect this the operator begins by rubbing it briskly with a pad of absorbent cotton-wool that has been steeped in ligroine. He next rolls it loosely in a single layer round small glass rods or tubes and places these in a flask of ligroine where he leaves them for about 20 days. The rods are then taken out and exposed to the air for about 24 hours or until the ligroine has evaporated. They are then placed in a 2 per cent. solution of iodo-acetone contained in a wide-mouthed yellow flask (previously sterilised by means of boiling water) which must be kept hermetically closed. After standing for a month in a dark place the rolls of catgut are transferred with sterilised pincers to a flask of 90° alcohol for storage until required. When first taken out of the iodo-acetone the catgut is hard and somewhat brittle but the spirit soon removes the excess of iodine left by the evaporation of the acetone and restores flexibility. In order to test the sterility of the iodo-acetonised catgut specimens were soiled with various cultures, including staphylococcus aureus, streptococcus pyogenes, the bacillus of Yersin, bacillus subtilis, and bacillus mesentericus, and in every case sterility was perfectly maintained. Even when trampled under foot the ligatures did not lose their neutrality. Iodo-acetone vapour irritates the conjunctiva and causes excessive lacrymation but this defect is removed by the alcohol.

A TELEGRAM from the Governor of Hong-Kong received at the Colonial Office on April 18th states that for the week ending April 14th there were 21 cases of plague and 23 deaths from the disease. For the week ending April 21st there were 44 cases and 37 deaths. At Brisbane the official bulletin of the Department of Public Health, Queensland, states that for the week ending March 17th no case of plague was notified, the last case notified having occurred on March 6th.

THE King has granted to Mr. Reginald Gower Kirton, M.D. Lond., principal medical officer of the Egyptian Prisons Administration, His Majesty's Royal authority to wear the Insignia of the Fourth Class of the Imperial Ottoman Order of the Osmanieh, which decoration has been conferred upon him by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey, in recognition of valuable services rendered by him.

THE King has been graciously pleased to sanction the following appointments to the Order of the Hospital of St. John of Jerusalem in England:—To be Knights of Grace: John Samuel Griffiths, M.R.C.S. Eng., L.R.C.P. Lond.; Ernest Laurie Robinson, M.R.C.S. Eng., L.R.C.P. Lond.; Surgeon-Lieutenant-Colonel Frederick William Gibbon, V.D.; and Surgeon-Lieutenant-Colonel Edward Cureton, V.D.

THE President of the Local Government Board, accompanied by his private secretary and Dr E. J. Steegmann, secretary to the Royal Commission on Tuberculosis, visited on Friday the farms and laboratories at Stansted, Essex, where the research work of the Royal Commission is being carried on, with the generous coöperation of the proprietor, Sir James Blyth.

THE festival dinner of the City of London Hospital for Diseases of the Chest will be held at the Trocadéro Restaurant, Piccadilly-circus, London, on Friday, May 11th, at 7 P.M. The Lord Mayor of London will take the chair and all communications should be made to the secretary at the hospital.

Baron Takaki, F.R.C.S., Surgeon-General of the Imperial Japanese Navy, will deliver a series of lectures at St. Thomas's Hospital on May 7th, 9th, and 11th, at 5.30 P.M., upon "The Preservation of Health Among *Personnel* of the Japanese Army and Navy" based on his experiences in the late Russo-Japanese war. The lectures will be of the greatest interest and applications for tickets should be made to Mr. G. Q. Roberts, Secretary's Office, Medical School, St. Thomas's Hospital, London.

Professor G. Sims Woodhead will give an introductory address, entitled "Past and Present: the Pathology of Skin Diseases," at the opening of the summer session at St. John's Hospital for Diseases of the Skin, Leicester-square, London, on Tuesday, May 1st, at 5 P.M.

THE President of the Local Government Board has appointed Mr. A. W. J. MacFadden, M.B., C.M. Edin., D.P.H., late medical officer of health of Edmonton, to the office of assistant inspector of foods in the medical department of the Board.

Sir William Collins, M.P., will give an address on Monday evening next, April 30th, at 8 o'clock, at the Royal Eye Hospital on "The Study of Ophthalmology; its Relation to General Medicine and Surgery."

THE annual dinner of the Pharmaceutical Society of Great Britain will be held at the Whitehall Rooms of the Hotel Metropole, London, on Tuesday, May 15th, at 7 P.M.

THE annual general meeting of the London and Counties Medical Protection Society will be held on Friday next, May 4th, at 4 30 P.M., at 31, Craven-street, Strand, London.

THE annual dinner of the Chelsea Clinical Society will be held at the Criterion Restaurant, Piccadilly Circus, London, on Thursday, May 3rd, at 7.45 P.M.

THE annual dinner of the Royal Sanitary Institute will be held in the Langham Hotel, Portland-place, London, on Wednesday, May 9th, at 7 P.M.

THE annual general meeting of the Medical Defence Union will be held on Thursday, May 17th, at 4 P.M., at the Grand Hotel, Birmingham.

VACCINATION EXPENDITURE.—At the meeting of the Tiverton (Devon) board of guardians held on April 10th it was stated that during the three years preceding the passing of the Vaccination Act the cost of vaccination in the Tiverton union was £150, whilst for the five years after the passing of the Act the fees amounted to £900.

UNIVERSITY COLLEGE, READING.—We have received the new prospectus of this college which was founded in June, 1892. The college consists of departments of letters and science, agriculture, horticulture, music, the fine arts, and commerce, and provides teaching for about 1500 day and evening students. It is affiliated to the University of Oxford and is recognised by the Board of Education as a day training college and by the Royal Colleges of Physicians of London and Surgeons of England as a place of instruction in natural science. In addition to lecture and class rooms it contains zoological, botanical, chemical, physical, and bacteriological laboratories, art studios, students' library, and common rooms. The spring term commenced on April 25th. The autumn term will commence on Oct. 24th. Full particulars of the courses of study are given in the college calendar, which can be obtained (price 1s., post free) on application to the registrar, University College, Reading.

THE FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

Held at Lisbon, April 19th—April 26th, 1906.

THE Fifteenth International Congress of Medicine was opened in Lisbon on Thursday last, April 19th, under the patronage of the King and Queen of Portugal. The arrangements of the Congress have been made by an Executive Committee assisted by a large committee of organisation, and, as our Special Correspondents on the spot have been able to report, these arrangements have worked thoroughly well.

The President of the Congress is M. Costa Alemão, and the Executive Committee consists of the President; Professor Miguel Bombarda, the general secretary; M. Alfredo Luiz Lopes, the treasurer; M. Antonio de Azevedo, M. Mello Breyner, M. Azevedo Neves, and M. Mattos Chaves, assistant secretaries; M. Annibal Bettencourt, Professor Clemente Pinto, Professor Daniel de Mattos, Professor Ricardo Jorge, M. Silva Carvalho, and M. Zeferino Falcão. All these gentlemen were on the committee of organisation, where they were assisted by some 36 other prominent Portuguese professors and men of science.

The Congress was formally opened by the King, who was accompanied by the Queen and Queen Dowager, at the Salle de la Société de Géographie, where the section of Colonial and Naval Medicine was to hold its meetings and where a colonial exhibition of considerable interest had been organised. The representatives of no less than 24 nationalities replied to the official welcome extended to their countries, and the proceedings closed with an eloquent speech from President Ribeiro, the new Premier.

On the same evening an inaugural reception was held at the new School of Medicine, where a scanty attendance on the part of British congressists was attributed to the absence of all who had travelled by the *Ophir*, the passengers of which were unable to land.

Work began in the sections on Friday morning, while in the afternoon members of the Congress were invited to a reception by Sir Francis Cook (Viscount Monserrat) at his magnificent gardens near Cintra.

THE INAUGURAL CEREMONY.

(FROM OUR SPECIAL COMMISSIONER.)

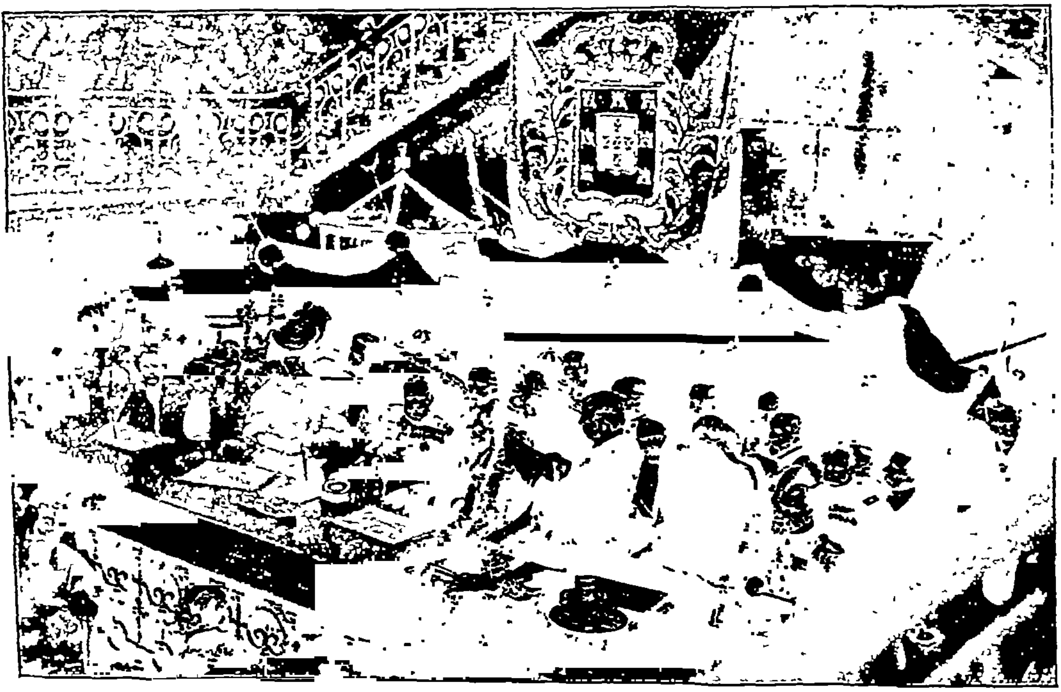
Lisbon, April 20th.

The Geographical Society possesses a long room or hall which serves as a museum. It is surrounded by glass cases containing curios and is lofty enough to have two galleries going all the way round. Its main support consists of iron girders and pillars; in fact, it looks something like the machine gallery of a theatre. It is possible to crowd a great number of persons in these two galleries and on the floor of this vast hall but the general effect is not impressive. Shortly after half-past one on Thursday afternoon the Government representatives began to gather upon and round the platform. As many were army surgeons they wore their uniforms and these, together with the university gowns which the British contingent largely affected, lent a more lively tone to the scene. The platform was raised scarcely two feet from the floor and was quite level. The distinguished members who crowded this small and but slight elevation hid each other from the great mass of spectators and members sitting in front. It is obvious that a platform should slant so that those who sit at the back can see and be seen. We may abuse the Madrid Congress but it is doubtful whether there was ever such a brilliant scene as that of the opening ceremony. This, it will be remembered, was held at the Grand Opera House where the huge and slanting stage was converted into a platform by being walled in with gigantic carpets from the State factory. Undoubtedly a large opera house is admirably suited for ceremonies of this description, a fact brought home to me when I recalled the ceremony at Madrid three years ago and compared it with that of to-day. It is true that we are not so numerous on the present occasion but nevertheless the great hall of the Geographical Society was quite filled with a number of ladies as well as gentlemen. From the end furthest from the platform a string band had difficulty in making itself heard amid the clatter of so many voices and different languages.

Soon after 2 o'clock, and in spite of the noise, the crowd became aware that the band was playing the national anthem and therefore surmised that the King must have entered. Soon His Majesty Dom Carlos was seen walking up the centre of the hall. Three monumental chairs had been placed behind the table on the platform. The King occupied the central chair, on his right sat Her Majesty the Queen and on his left the Queen Mother. The Royal party were flanked on the right by the President of the Congress, Councillor Costa Alemão, and on the left by the general secretary of the Congress, Professor Miguel Bombarda. A few representatives of foreign Governments who happened to be near at hand were presented to the King. There then ensued a moment of deep silence and expectancy which was only broken when the King, in a clear resonant voice and speaking the purest French, began his address.

HIS MAJESTY first rendered homage to the labour to be undertaken by the Congress. This he did in the name of the whole nation because he was its supreme magistrate. He offered an open-hearted and cordial welcome to all the members of the Congress who had come from so many different countries to Portugal. In Portugal all were animated with the desire to share in such work as that of the Congress. They were inspired with feelings of solidarity and fraternity towards other nations. There was the religion of duty, the duty of the citizen to the State to which he belonged, the duty of the State towards other States. To relieve suffering and pain was the great work of the members of the Congress and the State must help in this beneficent work. The members of the Congress would relate what they had done, how they had fought against a multiplicity of evils, and the victories they had won. By such endeavours they had saved more lives than wars had destroyed. At times their progress was slow but it was irresistible in its action. Peoples were citizens of the world and each nation must do its duty towards other nations, so as to facilitate the realisation of the measures and principles necessary to preserve life. Personally, His Majesty insisted that he was an ardent student of the natural sciences and therefore was fully able to understand and to admire the work of the men of science who were attending the Congress. His beloved Queen had, on her side, taken so active a part in organising the struggle against tuberculosis that she had by her acts proved how much she was at heart with the work of the Congress. His Majesty concluded by saying that he was proud to preside over such an assembly and that the advent in Lisbon of so many distinguished men was an honour to Portugal. He then declared the Congress open.

The speech was warmly applauded, especially the reference to the endeavours of the Queen in helping to provide means for the struggle against tuberculosis.



Scene at the opening ceremony of the Fifteenth International Congress of Medicine. Professor Bombarda, Secretary General, is reading the inaugural statement. The Queen, in white, is sitting on the King's right and beyond her is Dr. Costa Alemão, President of the Congress. Dr. Pavy may be recognised in the *foreground*.

Councillor COSTA ALEMÃO, who spoke next as President of the Congress, expressed his gratitude to the King and the Royal Family for their help and then thanked the members of the Congress for their attendance.

Professor MIGUEL BOMBARDA, as secretary general of the Congress, followed and read out a mighty array of statistics showing how many papers and reports had been contributed to the Congress and how much had been done to render it a success. He managed to make a few compliments to the different nationalities represented, to the England of Harvey and the France of Pasteur, nor did he forget Japan which was represented on the platform by Dr. Oishi. The celebrated Japanese bacteriologist, Dr. Kitasato, was expected to attend but has unfortunately been detained.

Now commenced the apparently indispensable speeches from the different nationalities. The speeches are taken in the order of the alphabet according to the French titles, so that Germany began.

Professor W. WALDEYER of Berlin concluded his remarks by saying that as the Portuguese navigator had named the Cape of Good Hope in anticipation that he would discover the sea route to India, so also had they the good hope that this Congress would lead to new and important discoveries in medicine.

Professor H. **OBERSTEINER** then spoke for Austria and was followed by the representative of the Argentine Republic.

Dr. **DEJACE** spoke for Belgium and hoped that during the twentieth century there would be no other war than the war against disease. Then came in rapid succession the spokesmen for Bulgaria, Chili, Colombia, and Denmark. Dr. C. **CORTEZO**, on behalf of Spain, where the last Congress had been held, alluded to the great interest taken in Spain in the arduous work of organising the present assembly.

Dr **RICHARD** spoke for the United States and praised the beauty of Portugal and Lisbon.

Professor **CORNIL** spoke for France and Sir **DYCE DUCKWORTH** for Great Britain. The latter elicited loud applause by addressing the Royal Family and the Portuguese people in Portuguese. He urged that the pursuers of scientific knowledge were above the strife of politics and in the name of his countrymen, and his countrywomen also, he thanked the Portuguese for their warm-hearted welcome.

The representative of Greece who followed naturally claimed to be the fellow countryman of Hippocrates. The Hungarian spokesman alluded to the effects of such congresses in enabling men of science to meet and to encourage each other.

As usual, the Italian representative was really eloquent. Dr. **SANTINI** spoke in his own beautiful language and his sentences rang out as sweet music; and though not many persons present understood fully what he said, still he stirred his audience by such oratorical sentences as the following: "Ed è altresi per me ragione di onore e di letizia porgere alla splendida Lisbona, la vetusta e vaghissima Regina di Occidente, città Principe della Lusitania, che tante vanta radiose glorie nei fasti più puri delle colonizzatrice civiltà, ed è alle sorelle latine genti carissima, l'affettuoso saluto di Roma italica, dell'ALMA MATER, la quale infra il fiorente rinascimento di ogni terra latina, oggi, quasi più che secolare madre, ama delle latine genti nomarsi sorella amorosissima." When, finally, he concluded with further salutation to the land of Vasco de Gama from the land of Christopher Columbus he fairly brought down the house. Japan was represented by Dr. Shigekichi Oishi of the Imperial Japanese navy, and the mere mention of the word Japan sufficed to bring forth loud applause. Then came in rapid succession the representatives of Mexico, Monaco, Norway, and Dr. Pineaple for the Netherlands, who brought the good wishes of the Queen of Holland for the success of the Congress. Like the Portuguese, the Dutch, he said, were great navigators and claimed the ocean as their common mother.

The Roumanian representative, however, capped this by asserting that the Roumanians and the Portuguese belonged to the same Latin stock and said that he had been struck by the many things he had seen in Portugal which reminded him of his native Roumania. Now came the delegates of Russia, Sweden, and Venezuela. The Venezuelan was the twenty-fourth nationality speech and it was with a sigh of relief that the Congress heard that the representatives of the other nations were absent or had foregone their right to speak.

Professor **POSNER** of Berlin then rose as the newly elected President of the International Association of the Medical Press. Though a German, Professor Posner spoke in French because French is the official language of the association He explained that the association which he represented had held its general assembly during the last two days in Lisbon and had commissioned him to express the goodwill of the medical press towards the Congress. Under its present eminent patronage the Congress was sure to be a success An international movement, based on the desire to group together the medical journals of the world, had in the persons of its principal representatives come to pay homage to the Portuguese people. With the efficient aid of Professor Miguel Bombarda they had successfully accomplished their mission. That this should be so was a matter of importance for the Medical Congress. Now that the press had done its business it was quite ready to attend to the business of the Medical Congress and would echo in all countries whatever beneficent work might be accomplished at Lisbon for the greater good of humanity.

This speech, which was well received, was followed by an address from His Excellency Senhor **HINTZE RIBEIRO**, Premier and President of the Council of Ministers. Perhaps the opening passage of this speech gives the best idea of the eloquence of the Premier of the "Conservative-Progressive" Government which came into office only a few weeks ago. The Premier said:—

"Sire, Majesty,—More than many other homages, those of the messengers of universal science will have rejoiced your heart. In your memory the stirring words just pronounced will ever remain engraved. You may be well pleased with them. You, Madame, who have chosen medicine for the ally of your generous benevolence in the holy crusade against afflicting scourges; you, Madame, who have always and everywhere distributed the most beautiful flowers of that sublime virtue which is called charity; you, Sire, whose mind is ever alert, and who as a learned and humanitarian monarch have been so good as to address in person your august salutations to this pilgrimage of science—you have inaugurated, by words that will ever remain memorable, this cosmopolitan work of peace and solidarity in which sentiment and intelligence surpass each other so as to increase the value of health and of human life." The Premier concluded his oration by quoting the great Portuguese poet, Camoens, when he said that "to medicine would come a new light." This might serve as a motto for the Congress and if the new light came on the present occasion then it would carry the name of Portugal all over the world.

The Royal party rose and slowly wound their way through the crowd out of the great hall, stopping on the way to talk to some of the members of the Congress. There was now a little interval for rest or for seeing some of the sights between the conclusion of the inaugural meeting and the reception which the President of the Congress was to give later in the evening.

Reception at the New School of Medicine.

In the evening of Thursday, at the New School of Medicine, all the members of the Congress were received by its President, Councillor Costa Alemão. This is the first time that a large number of persons have penetrated this building, which is so new that it can scarcely be said to be quite finished. The chairs had only been brought in during the day. The bareness of the walls was concealed by artistic silks and tapestries, while here and there a handsome carpet had been unrolled on the floor at the very last moment. Indeed, for those who had seen the place a few days ago it is wonderful how much has been done in a very short time. In the central court the band of the Municipal Guards, which is one of the best military bands in Portugal, discoursed sweet music all the evening. It played, among other things, an international march composed of several national anthems. At the top of the building there was a buffet which many congressists did not find out but to which others did full justice. The chief pleasure, as is usual on such occasions, is the meeting of old friends and the making of new acquaintances. In this respect it was particularly noticed that the large portion of the British contingent that came by the *Ophir* were not present. Apparently these passengers are in no wise satisfied. They say that the boat was overcrowded and that there were not enough stewards on board to attend to their needs. Perhaps some of the complaints are exaggerated, but if half of what I have heard is true then they must have had an unpleasant time. One thing, however, is certain. The ship is moored away from shore on the Tagus which here is so broad as to constitute an arm of the sea. To land is a matter of time and the boatmen charge extra when it is rough. Even the steam tender which plies backwards and forwards is a small boat and its passengers get splashed in bad weather. Therefore, yesterday evening the passengers remained on board the big ship and did not expose themselves to the bad weather, but in so doing they missed the reception at the School of Medicine. The Germans, on the contrary, are delighted with the *Oceana* of the Hamburg-American line, where they met with every attention, had excellent food, and plenty of cabin room. Further, instead of casting anchor in mid-stream, the German ship is moored alongside the Lisbon quay and the passengers go in and out freely day and night; in fact, the ship is as convenient as an hotel. The ships of the Booth Line also anchor in midstream, but, such being the case, they provided hotel accommodation on shore for all their passengers and have been assiduous in attending to them ever since. One *of their agents, Mr. E. Garland*, has indeed become very popular among the British visitors stranded here as strangers in a truly strange land. Complaint is made that at some of the hotels the Portuguese waiters are very incompetent and there is occasionally considerable difficulty in getting a meal served without much unnecessary loss of time. In regard to the *Ophir* I am told that the Congress committee in London made arrangements that the ship should come up alongside the river embankment as the *Oceana* has done. Further, it is stated that the money for the right to moor alongside was actually paid, when some persons suddenly conceived the idea that it would be dangerous to do so. There might be a sewer outfall close to the ship and it would not be safe to be so near the town. This is a matter on which the people at Lisbon feel very sore, they are very anxious to get some authorised pronouncement as to this supposed danger to ships that come close to the shore. In the meanwhile the mooring of the *Ophir* in mid-stream has been the cause of preventing a great number of the British members from assisting at the brilliant and pleasant reception held on the opening day of the Congress at the new School of Medicine.

THE SECTIONS BEGIN WORK.

April 21st.

On Friday morning the sections were to begin work at 8 30. Having by previous and extended experience of international congresses acquired some knowledge of what this might mean, I did not allow such futile announcements to disturb my sleep. It was nearly 9 30 in the morning when I reached the new School of Medicine Most of the persons who were already present were looking after their badges, guide-books, invitations to festivities, or buying picture postcards. Still, being now fully an hour behind the announced time, it seemed to me that I should make quite sure that nothing really important was going on in the sections. In that of Obstetrics, which occupies one of the largest rooms, I found just 15 persons including some ladies who had probably gone there because there were some pretty tapestry on the walls and comfortable chairs to lounge upon and to gossip for they did not belong to the section. Military Medicine has but a small room and that was already fairly well filled. The section had actually got to work, so that "military punctuality" is not a vain term after all. The section on Urinary Diseases was very scattered. A good many persons were there, perhaps 30 or 40, but they were all talking to each other. The best example of the effects of calling upon the sections to meet too early in the morning that came to my notice was in the Otological section. Here two members, and only two members, of the section had arrived. They had very wisely opened the window and stood out on a small balcony contemplating the magnificent view of the valley and the hill and castle of Lisbon beyond. It was delightful and they were also smoking very good cigars. In the Rhino-Laryngological section there were 11 members present but they had not opened the window and they only smoked cigarettes. The President occasionally stepped up to the table and gently tinkled a little silver bell but no one took the slightest notice, so the President left the table and the presidential chair to join in the general conversation. In the Pediatrics (surgical) section there were 14 persons and a German member was solemnly reading a long paper to them. By this time it was nearly 10 o'clock which is the earliest hour at which it is practicable to begin work considering the difficulties that assail strangers living in crowded hotels; therefore I proceeded to my own section—that of Hygiene—which I found had just begun business with an audience of 20 persons. The number, however, soon increased and we had an interesting discussion which I hope to describe on a subsequent occasion.

All the sections adjourned early so as to join in the excursion to the magnificent gardens of Sir Francis Cook at Monserrat, near Cintra, so it does not appear that very much work was done anywhere. In the Dermatological section I am told that nothing of importance is expected. There are not many papers and of these several have already been published. The members of the section do not seem to think that they can instruct each other and so I rather fancy the meeting and discussions will not be prolonged in this section but its members will have more time to enjoy the beauties of the country.

During the first morning the subject discussed in the section on Therapeutics was the Effect of Exercise on Arteriosclerosis. In the section on Neurology, Professor **RAYMOND** of the Salpêtrière Hospital read a good paper on the Danger of Mercury in the Treatment of General Paralysis.

To-day, Saturday, there was no attempt to start the work of the sections at too early an hour. Consequently they were better attended when they did commence business. Also, the members have now got most of the tickets and other things that they wanted, so were able to get to work with greater facility. A considerable number of important papers were read to-day, and there was a very ardent debate at a mixed meeting of the fourteenth and seventeenth sections on the Prophylaxis of Yellow Fever. This afternoon the first of a large series of lectures and demonstrations was given, including a very interesting report on the above subject by Professor Rubert W Boyce of the Liverpool School of Tropical Medicine. So that now it may be said that the Congress has got fairly into harness. If the sections have been somewhat dilatory it is the fault of the members themselves. So far as the organisation of the Congress is concerned, all was ready for them. Nor have I, as yet, heard any complaints concerning the management in general of the Congress. It is, perhaps, too soon to say much about this but so far all promises well.

THE SECTIONS.

GENERAL PATHOLOGY, BACTERIOLOGY, AND PATHOLOGICAL ANATOMY.

Professor **HANS CHIARI** (Prague) read a paper upon

The Relations between the Pancreas and Fat Necrosis.

He said that this condition was given its present name by Balser in 1882. An extensive literature on the subject has appeared since that time and numerous experiments prove that fat necrosis is etiologically dependent on the action of the proteolytic ferment and the fat ferment of the pancreatic juice in presence of certain pathological changes in the pancreatic tissue. Wounds of the pancreas must obviously permit its juices to escape, but quite apart from this if there is any deterioration (*Schädigung*) of its structure and if juice possessing functional activity continues to be formed this secretion may disintegrate the deteriorated cells and by means of this tryptic self-digestion the pancreatic juice may arrive at the exterior of the gland. There exist in the pancreas some special conditions which do not occur in any other considerable gland but are to some extent represented in the phenomena of pepsin self-digestion of the stomach, a condition which may result from a great number of causes leading to deterioration of the walls of the stomach and failure of them to resist the action of the gastric juice. This tryptic self-digestion of the pancreas does not necessarily produce identical effects on the general health of the individual. On the one hand, the consequences may be extremely serious, such as extensive hæmorrhage into the pancreas and its vicinity, the formation of hæmorrhagic cysts in the position of the pancreas, localised or diffuse necrosis of the pancreas, suppurative pancreatitis due to the admission of bacteria, and the development of pancreatic sequestra, all this being very often associated with abundant fat necrosis. On the other hand, the tryptic self-digestion of the pancreatic tissue may be insignificant in extent, the fat necrosis may be harmless, and in course of time the symptoms of a lesion of the pancreas may disappear. Not much is known regarding the etiology of the stage preceding the self digestion of the pancreas. The severe cases are most frequent in corpulent persons and habitual drunkards. The connexion between true inflammation of the pancreas and self-digestion requires further elucidation.

Dr. **ERNEST FRANCIS BASHFORD**, director of the laboratory of the Imperial Cancer Research Fund, London, read a paper upon

The Classification of the Sarcomata.

He said that the sarcomata were connective-tissue new growths as distinguished from the carcinomata which were epithelial new growths. Sarcomata with all the features of malignant new growths were found throughout the mammalia and in marine fishes living in a state of nature. They had therefore the same zoological distribution as the carcinomata. Sarcomata, if they occurred in inaccessible sites, were clinically indistinguishable from carcinomata. Experimentally sarcoma was as difficult to transfer to another individual as carcinoma, and indeed the complete demonstration of the transmission of a sarcoma from one individual to another has not yet been furnished. There was no evidence that the sarcomata were infectious new growths. Carcinoma and sarcoma had so many features in common that they were probably manifestations of an identical or similar process in the epithelial and connective tissues respectively. The demarcation of the sarcomata from the granulomata, which were also new growths of connective-tissue origin, was not easy. By microscopical and clinical examination alone it was not possible to determine in some cases to which group a tumour should be assigned. Tumours have frequently been described as sarcomata when in reality they were infective granulomata yielding a high percentage of success in transmission experiments. Inoculation therefore afforded a means of recognising the true nature of some doubtful new growths and of establishing definite distinctions between the sarcomata and those forms of infective granulomata of which the specific causative organisms have not yet been isolated. The same method might also be expected to throw light on the relation, if any, existing between the various forms of leukæmia, Hodgkin's disease, chloroma, and other obscure conditions associated with enlarged lymphatic glands, and sarcoma on the one hand and granulomata on the other. The classification of the various forms of the sarcomata at present in vogue was morphological and histogenetic. For growths with well-marked differentiation, such as osteo-sarcoma or chondro-sarcoma, it was doubtful if in the present state of knowledge a more satisfactory classification could be devised.

Professor ERICH MARTINI (Berlin), staff surgeon in the German navy, read a paper upon

Trypanosomiasis.

After a general reference to human diseases in which spirochætæ were found and to the effects of trypanosomiasis affecting the lower mammals, birds, fish, &c., he proceeded to consider the latter disease in the human subject under the two headings of African trypanosomiasis and kala-azar. African trypanosomiasis was known as trypanosoma fever in its early stages and sleeping sickness in its later stages. It was conveyed by the glossina palpalis and was an exclusively African disease. Kala-azar and other febrile cachexiæ caused by the same parasite occurred principally in India but have been seen in Africa as well. The first account of sleeping sickness was published in 1803 by Dr. T. M. Winterbottom who had observed it in Sierra Leone. It has occasionally been conveyed to America by imported negroes but has never spread there. The parasite was discovered by Dr. J. S. Dutton and Mr. R. M. Forde in 1901. The preliminary latent stage might vary from two to eight years; the onset of the sleeping sickness stage was followed by death in from four to eight months. No method of immunisation was possible and prophylaxis depended entirely on the use of mosquito nets, wire gauze, and gloves as a protection against the glossina. Treatment consisted only in the use of palliative measures. Kala-azar (*Anglice*, black fever) was so called because in the early stages the patient's skin was sometimes pigmented. A considerable number of observers have taken part in elucidating the pathology of the disease. Although the insect by which the parasite was conveyed has not been positively identified the methods of prophylaxis recommended against African trypanosomiasis might be tried. No specific treatment was known. The patient's diet must be carefully selected on account of the frequency of intestinal complications.

Dr. A. LAVERAN (Paris) read a paper upon

Prophylactic Inoculations against Protozoal Diseases.

He discussed the subjects under the three heads of malaria, piroplasmosis, and trypanosomiasis. With regard to the first it was well known that negroes, although by no means exempt from malaria, nevertheless thrived in countries so malarious as to be uninhabitable for persons of other races. This partial immunity was peculiar to the negro and there was no evidence of its occurrence among the natives of the malarious regions of Europe. Various forms of piroplasmosis occurred in cattle, sheep, dogs, and horses. There were two forms of bovine piroplasmosis—namely, Texas fever and Rhodesia fever. Animals which have survived an attack of either variety were immune against that variety but not against the other. Texas fever did not attack native cattle but imported cattle died from it in large numbers. Various attempts, more or less successful, have been made to produce immunity by inoculating healthy animals with the blood of convalescents. Animals might be infected with the trypanosoma Gambiense or parasite of human sleeping sickness, but those which recovered were not rendered immune. Rats, on the other hand, might be easily immunised against the trypanosoma Lewisi.

Dr. SWALE VINCENT, professor of physiology in the University of Manitoba, read a paper upon

Internal Secretion and the Ductless Glands.

He said that the term "internal secretion" seemed to have been first used by Claude Bernard who, in his "Leçons de Physiologie Expérimentale" described the glycogenic function of the liver as the *sécrétion interne*, while he referred to the preparation of the bile as the *sécrétion externe*. The structures usually included at the present time under the title of ductless glands were the thyroid gland, the parathyroid glands, the cortical suprarenal gland, the medullary suprarenal gland, the pituitary body, the carotid and coccygeal bodies, and possibly the thymus. It was believed that these ductless glands manufactured and poured, directly or indirectly, into the blood stream some substance or substances which were of service to the economy, either by supplying a need or by destroying other substances which were needless or positively harmful. This last function was usually ascribed to the thyroid and parathyroid glands; the theory obviously assumed the existence of a process of auto-intoxication. In his summary of the theories which have been proposed as to the function of the suprarenal capsules Professor Vincent said that the two chief theories were (1) the auto-intoxication theory and (2) the theory of internal secretions. The former was supported by Abelous and Langlois, who believed that toxic substances, the products of muscular metabolism, tended to accumulate in the organism and that the function of the glands was to remove or to destroy these. The internal secretion theory, on the contrary, asserted that the suprarenal capsules were continually secreting into the blood an active material, adrenalin, which was of benefit to the muscular contraction and tone of the cardiac and vascular walls and even of the skeletal muscles. Although the theory of internal secretion appeared to have the balance of probability on its side, the direct evidence in favour of the secretion of material into the blood-stream was, however, very slight. The auto-intoxication theory would seem to require the assumption that adrenalin was a waste product soon about to be eliminated, while the internal secretion theory supposed that it was a product of glandular activity manufactured for use in the economy. It was not yet possible to express definite opinions on the subject.

Staff-Surgeon Professor ADOLF DIEUDONNÉ (Munich) read a paper on

Prophylactic Inoculation against Infectious Diseases.

He said that the procedures employed for this purpose were (1) inoculation with virulent living pathogenic microbes; (2) inoculation with attenuated living pathogenic microbes; (3) inoculation with dead bacteria; and (4) inoculation with bacterial extracts. The first-mentioned of these was but little used; the second was exemplified by vaccination for small-pox and by antirabic treatment; the third was applied on a large scale against cholera, enteric fever, and plague; and the various forms of treatment by tuberculin were the principal examples of the fourth. Inoculation with dead bacteria was first attempted in the human subject by Kolle. He found that specific protective substances (bacteriolysins and agglutinins) were produced in considerable quantity after a single injection of small quantities of dead cultures grown on agar and that the existence of these protective substances was perceptible even a year after the injection. As a prophylactic against cholera and plague Haffkine used bouillon cultures several weeks old; and as a prophylactic against enteric fever, Professor A. E. Wright used bouillon cultures which after growing for 48 hours had been killed by exposure to a temperature of 65° C. Professor Dieudonné gave some account of the results obtained from the inoculation against enteric fever of German soldiers sent to South-West Africa since January, 1905 More than 5000 men were inoculated, usually between the collar-bone and the nipple. With most of them the general reaction with malaise and a temperature rising as high as 39° C. took place in from two to five hours, but these symptoms completely disappeared in from 12 to 16 hours and the local effects did not remain longer than 48 hours. When enteric fever made its appearance the mortality was 4 per cent. among the inoculated and 11 per cent among the uninoculated. Among the uninoculated the proportions of severe and mild cases were respectively 25 and 42 per cent, whilst among the inoculated the proportions of severe and mild cases were respectively 10 and 66 per cent.

MEDICINE.

The Treatment of Cirrhoses of the Liver.

Dr. R. SAUNDBY (Birmingham) read a communication on this subject. He said that it was a question whether interstitial hepatitis in itself gave rise to any symptoms which attracted attention other than the mechanical disturbance of the circulation. The main symptom of importance which really depended upon the hepatitis was ascites. Coincidently with the obstruction in the liver of the portal circulation a collateral circulation developed and as the progress of the hepatitis was slow it was probable that but for some accident occurring this collateral circulation would always be compensation enough for the ordinary portal circulation to prevent ascites. Sudden congestion of the liver from an alcoholic debauch was the most common cause of the equilibrium being upset. When fluid had been poured out into the abdominal cavity it constituted a hindrance to the venous circulation by raising the intra-abdominal pressure. For this reason diuretics were useless to remove the fluid and hydragogue cathartics might set up a fatal enteritis. Paracentesis was therefore the best method of removing the fluid. It should be performed as soon as the fluid had accumulated sufficiently to cause discomfort and should be repeated as often as the fluid re-accumulated. By repeated punctures there was fair prospect of re-establishing the circulation. When repeated tapping was not successful in preventing the return of the dropsy the Talma-Morison operation might be performed. This consisted in opening the abdomen and stitching the omentum to the abdominal wall, so as to increase the area of the collateral circulation. Prolonged drainage after the operation did not seem to be justifiable. But the value of the operation should not be over-estimated and as a rule simple repeated tapping sufficed. Where, however, this did not suffice the Talma-Morison operation was indicated. It was not fair to postpone it until the patient was moribund As for hæmatemesis, which was the other symptom directly dependent upon the hepatitis, it and ascites were mutually exclusive and rarely occurred in the same individual except just before death. The treatment of hæmatemesis was purely palliative and consisted in rest, abstinence from food, and the application of an ice-bag, together with a hypodermic injection of morphine.

The International Prophylaxis of Tuberculosis

M. SAMUEL BERNHEIM (Paris) read a paper upon the above subject. He referred to the notice taken of the matter at the Congress on Tuberculosis held in London in 1901 and to the formation of an International Bureau to deal with tuberculosis, the seat of which should be at Berlin, and to the foundation of the Société Internationale de la Tuberculose, which had its headquarters at Paris. Tuberculosis should be a matter for the consideration of international hygiene just as much as were plague, cholera, and yellow fever. The markedly free intercourse among various nations which was characteristic of these present times made it easy for tuberculosis to spread, and the disease was specially rife amongst those employed in traffic of all kinds, notably among sailors and among railway servants In the navy tuberculosis was common and its existence was made easy by the almost necessarily unhygienic conditions of life which exist on board of a modern battle-ship. It was also extremely common on modern cargo ships As regards land traffic, railways were responsible for the spread of tuberculosis to a marked degree. In fact, as Brouardel had said, "The railway industry has, as regards the spread of tuberculosis, an influence throughout the territory which is affected thereby, comparable to that exercised by the army and the navy." M. Bernheim's conclusions were as follows. The prophylaxis of tuberculosis should be an international matter. The most rigid rules of prophylaxis, even if accurately carried out, were useless if only applied to one country. Unless the neighbouring countries, or, indeed, those more distant, carried out the same or similar rules, prophylaxis in any particular country was rendered of no effect. Regulations for the international prophylaxis of tuberculosis should be laid down comparable to those already decided on at various international conferences, such as those at Paris in 1894 and at Venice in 1897, in regard to plague, cholera, and yellow fever. An international commission composed of authorised representatives of the various nations should be appointed and should compare the various regulations existing in the respective countries represented. Then an international code of prophylactic regulations against tuberculosis could be drawn up. "If," concluded M. Bernheim, "there is a question, which in its very essence is catholic and which merits the attention and watchfulness of the *savants* of the whole world, it is that of tuberculosis. But it will never be solved save by the union of the intelligence and the goodwill of all the nations."

The Pathogenesis of Arterial Hypertension.

Two papers were communicated to the Congress upon this important subject, the one by Dr. TRUNECEK (Prague) and the other by Dr. HENRI HUCHARD (Paris).

Dr. TRUNECEK pointed out that arterial hypertension could be divided into two great classes. The one was called spastic hypertension and was due to a narrowing of the calibre of the blood-containing vessels; the other was called plethoric hypertension and was due to an increase in the contents of the blood-vessels. One quality was common to both these types—namely, a rise in the blood pressure. Putting aside cases of congenital narrowing of the blood-vessels, or of a possible "plethoric habit," which had a theoretical rather than a practical value, he passed on to consider the pathological condition of hypertension. As to spastic hypertension its main cause was probably some alteration in the bio-chemical qualities of the blood. Its characteristic symptom was a pulse strong and full in the large arteries and hard and small in the little arteries. The arteries, especially those of medium calibre, became hard and tortuous. Moreover, in patients who had suffered for some time from hypertension various affections due to anæmia arose. Thus cerebral anæmias gave rise to transitory aphasias or paralyses. Pectoral anæmia gave rise to anginas. Abdominal anæmia gave rise to alternations of diarrhœa and constipation or to a discharge of urine at one time of low specific gravity, abundant and limpid; at another scanty, concentrated, and full of urates. Peripheral anæmia gave rise to the well-known phenomena of "dead fingers." With regard to plethoric hypertension its mode of origin was very obscure. It might be divided into polycythæmic plethora and serous plethora. Its characteristic symptom as compared with spastic hypertension was a pulse strong and full in the great and little arteries. The capillaries and veins were distended and the arteries were neither hard nor tortuous.

Dr. HENRI HUCHARD commenced his paper by saying that the subject of arterial hypertension had occupied him for many years, and more especially as it affected the heart. The results of arterial hypertension naturally divided themselves into three sections—the physiological, the pathological, and the therapeutic. As to physiology, compression of an artery diminished the blood pressure on the distal side of the point of compression and increased it on the proximal side, this increase being proportional to the calibre of the artery and consequently to the flow of blood through it. The heart, however, could adapt itself to varying pressures. Experiments had shown that if the arterial tension were constantly augmented the cardiac valves became œdematous and exhibited punctiform hæmorrhages. Vascular tone depended not only upon the myocardium, the mass of the blood, and the vessels, but also upon the action of certain glands. Some glands, such as the suprarenal body, secreted a hypertensive substance; others, such as the thyroid body or the liver, secreted a hypotensive substance. As to pathological consequences, arterial hypertension could, and did, produce arterio-sclerosis, the various circulatory troubles which were often so evident at the menopause and at puberty, migraine, and, in addition, arterial hypertension had a most injurious effect upon aneurysms. The condition also played its part in lead poisoning, gout, diabetes, hæmorrhages, of which it may be either the cause or the cure, Raynaud's disease, and various "neuralgias." The gastric crises in tabetic subjects were often preceded by a rise in the blood pressure, and in heart disease and affections of the vessels its influence was most marked. In the brain it gave rise to cerebral hæmorrhages and to the transitory aphasias seen in pregnant women or in those affected with arterio-sclerosis. Increased arterial tension may also be the cause of sudden attacks of cardiac dilatation seen in acute infectious disease and especially in scarlet fever. As to therapeutics, hygienic measures were of the first importance. The diet should be principally milk or milk and vegetables or a simple "dechloridated" *régime*. Of drugs the most useful were the nitrites. The working of the kidneys must be carefully watched and to assist the elimination of urinary toxins theobromine was exceedingly useful. Ovarian extract might be of use in the *arterio-scleroses* of the menopause. Although many medical men believed that calomel in small doses could lower arterial tension Dr. Huchard did not feel the same confidence in the use of that drug.

Cerebro-spinal Meningitis.

Dr. JUDICE CABRAL (Lagos) communicated a long paper upon this subject. The paper was really a monograph upon epidemic cerebro-spinal meningitis and we cannot do more in the space at our command than indicate the main points of what was an exhaustive essay upon the disease in question. Dr. Cabral commenced by dividing the various forms of meningitis by the method of dichotomy into those that were tuberculous and those that were not. He then gave the differential points of diagnosis between these two forms. With regard to the non-tuberculous forms of meningitis these again might be divided into two groups. In the one came epidemic cerebro-spinal meningitis, the cause of which was a definite microbe, the diplococcus intracellularis of Weichselbaum, and those due to the pneumococcus, the streptococcus and other microbes, not appearing secondarily to the incidence of the microbe on the pulmonary system or elsewhere, but as primary affections. In the other group were the forms of meningitis evidencing themselves as complications of other disorders, such as typhoid fever, influenza, and the specific fevers. Dr. Cabral then passed to consider the main subjects of his essay—namely, epidemic cerebro-spinal meningitis. He gave a historical retrospect of the disease and then discussed its etiology, the specific bacillus, and the influence of locality, season of year, sex, occupation, and personal conditions, such as lactation and pregnancy. Methods of invasion, the question of contagion (on the whole, it would seem that the disease was contagious), were next considered. The general and special symptomatology were then dealt with from observations upon 178 patients seen during the epidemic in Portugal of 1901–02. As to the outcome of the disease, recovery with or without some organic or functional defect was the rule, but the death-rate was high—namely, 40 per cent. The average duration of the disease in cases which recovered was from 16 to 35 days. Dr. Cabral then described the post-mortem appearances, discussed the diagnosis and prognosis, and concluded with directions for treatment. In his opinion the best method was lumbar puncture either alone or followed by the injection into the spinal canal of a 1 per cent. solution of lysol or of cyanide of mercury. The application of leeches to the mastoid apophyses and wet cupping along the spinal column were also useful, as was the administration of calomel, opium, and the bromides. Large enemata (two litres) of plain boiled water or the same with the addition of a slight purgative might also be said to be almost always of service. The whole essay deserves the careful attention of medical men, worked out, as it is, from personal observation of a number of cases in a quite recent epidemic.

Professor ANTON WEICHSELBAUM (Vienna) read a paper upon

Cerebro-spinal Meningitis.

He said that in nosology this term was not applied in its widest signification but was restricted to the class of cases in which the disease assumed the epidemic form. Every variety of the disease which tended to become intermittent or chronic was caused by the micrococcus meningitidis cerebro-spinalis, an earlier name of which was the diplococcus intracellularis meningitidis. In a few cases of exceptionally acute type the disease has been caused by the diplococcus pneumoniæ and the streptococcus mucosus. The micrococcus was found principally in the meningeal exudation and in the mucus of the naso-pharynx. In epidemic times it might be found in the latter situation in persons who were suffering only from catarrh and had no symptoms of meningitis. It was therefore probable that the cavity of the naso-pharynx was the channel through which the micrococcus both found an entrance and was also conveyed from the sick to the healthy during the acts of sneezing, coughing, speaking, &c. As it had very little resisting power it was not likely to be dangerous when mixed with dust. The disease might be either sporadic or epidemic. Sporadic cases might occur year after year, often without any connexion between them being known other than the fact of vicinity. Epidemics never broke out suddenly. The disease extended itself gradually and chiefly in houses which were overcrowded, damp, dark, and not kept clean. Epidemics generally began in winter or spring; children and young persons were especially liable to be attacked. For the purpose of diagnosis cerebro-spinal fluid obtained by lumbar puncture must be subjected while perfectly fresh to microscopical and cultural examination.

PEDIATRICS.

M. CARLOS FRANÇA (Lisbon) read a paper on

The Varieties of Cerebro-spinal Meningitis.

The only useful classification of these varieties was one based on the causal agency in operation. He had adopted Osler's classification with slight modifications. Having recently dealt with a large number of cases of epidemic cerebro-spinal meningitis M. França gave a minute description of the malady and discussed each symptom separately with regard to its presence or absence in the other forms of meningitis. 271 cases of epidemic cerebro-spinal meningitis had been studied bacteriologically and in every case the typical diplococcus intracellularis of Weichselbaum had been isolated. With regard to the treatment M. França considered that the baths usually recommended, though undoubtedly beneficial, were so painful to the patients as to be often an impossible remedy. Lumbar puncture, on the contrary, was well borne and produced visible improvement. Great care was necessary for its proper performance. A fine platinum needle should be used one-quarter of a millimetre in diameter and 0·05 of a metre in length. The lateral decubitus was the position ordinarily recommended for the operation but M. França preferred to have the patient seated on the edge of the bed, the legs either hanging or bent and crossed and the trunk inclined well forward, thus producing the greatest possible separation of the lumbar vertebræ. A line joining the iliac crests passes across the fourth lumbar space and a line joining the postero-inferior iliac spines passes through the fifth lumbar vertebra. The needle is introduced a centimetre outside and a little above the arch above which the puncture is to be made. The needle should be directed a little obliquely up and in towards the median line; if no fluid comes at once slight rotation and withdrawal will cause it to appear. At the beginning of the malady puncture may be required daily, or even several times daily, according to the necessities of each case. In most cases from 40 to 50 cubic centimetres is sufficient to withdraw at one time. In several cases, after removal of from 25 to 50 cubic centimetres of cerebro-spinal fluid, injections of lysol (1 in 100) were made—from 12 to 18 cubic centimetres in the case of adult patients and from three to nine cubic centimetres in the case of children. M. França summed up his conclusions thus: 1. There are as many varieties of cerebro-spinal meningitis as there are microbes capable of living in the meninges. 2. The symptomatology of the different forms does not vary with the cause sufficiently to make diagnosis of the cause possible by that means. 3. Epidemic cerebro-spinal meningitis, caused by the diplococcus of Weichselbaum, is the only meningitis with a perfectly definite morbid entity. 4. The cause of the meningitis can be discovered only by the examination of the cerebro-spinal fluid. 5. The best treatment at present of the bacterial forms of cerebro-spinal meningitis (the tuberculous form alone excepted) is lumbar puncture, followed by antiseptic injections into the spinal canal. 6. Lumbar puncture is the curative treatment for non-bacterial forms of meningitis and is at least palliative in the tuberculous form. 7. Lumbar puncture is, and will be, the chief element in the diagnosis, prognosis, and treatment of the forms of meningitis.

Cerebral Palsy in Children.

Dr. GEORGE F. STILL (London) read a paper on this subject with special reference to etiology. His clinical observations had not led him to agree with the usually accepted theory that infantile hemiplegia was always of post-natal origin. Out of 49 cases investigated two were certainly congenital and seven were possibly, if not probably, congenital. Severe asphyxia at birth, in his opinion, was often undoubtedly a cause of idiocy and might reasonably also affect the motor centres. Asphyxia had occurred in 17 cases of spastic diplegia and in four of spastic paraplegia. 11 out of 25 cases of spastic paraplegia were born prematurely. Parental syphilis played but a small part in his statistics. It had been suggested that post-natal cerebral palsies were of infective origin, pathologically identical with acute anterior poliomyelitis, but infantile hemiplegia had not a similar seasonal incidence and epidemic occurrence and there were at present no scientific grounds for this assumption of identity.

Dr. M. A. BROCA (Paris) read a paper on

The Treatment of Abdominal Tuberculosis.

Only five years ago surgeons and physicians had pronounced almost unanimously in favour of surgical treatment for all cases of tuberculous peritonitis. Nowadays there was a reactionary party entirely in favour of medical treatment. The most recent surgical statistics showed positive cure two years after operation only in about 30 per cent. of cases operated upon. At the time when surgery was just coming to the fore Perrouo's statistics (1875 to 1888) of medical treatment showed a death-rate of 50 per cent.; of the remaining 50 per cent, 14 per cent. were lost sight of, 22 per cent. were only improved, and only 4 per cent. were positively cured. It was an indubitable fact that simple residence in hospital sufficed to cure many cases and certain surgical successes were in reality due to the medical after-care, proper food, air, and light obtained in a hospital. Many cases ran a benign course with spontaneous cure, and in France Alleaume, Grange, A. Martin,[1] and R Gœpfert had published statistics of cures after residence at the seaside; in Germany Rose[2] reported 52 cases, one-third of which were cured; and in America Guthrie[3] reported 41 cases; out of 14 operated upon seven had died and out of 27 not operated upon only four had died. All these statistics were untrustworthy because the after history of the patients had not been followed up for more than a year after apparent cure. The prognosis and treatment varied according to which of two great groups the individual case belonged to: (1) where the peritoneum alone was involved; and (2) where there were also present generalised lesions, acute, subacute, or chronic. Dr. Broca then discussed the several recognised clinical varieties of tuberculous peritonitis. Firstly, the form with more or less acute onset and rapid collection of ascites. This usually subsided rapidly, but if the absorption of fluid was slow it was probable that fibro caseous formation was taking place and laparotomy was then indicated, without peritoneal lavage or drainage. Secondly, there was a variety in which the ascites was encysted, hard and soft masses were palpable, and hectic fever was present. Little or nothing could be done for such cases either by physician or surgeon. Occasionally these cases healed spontaneously by passing on to a fibro-adhesive type. The surgeon should be on the watch for local abscesses which should be opened. Thirdly, there were peri-cæcal and pelvic varieties which required surgical intervention; sometimes simple laparotomy sufficed and sometimes removal of the tubes and ovaries was required Fourthly, surgical intervention was indicated in all cases with complications, such as intestinal obstruction, acute or chronic.

Professor ADOLPH LORENZ (Vienna) read a paper on

The "Bloodless" Treatment of Congenital Dislocation of the Hip

After some introductory remarks he proceeded to give a description of the technique of the operation, with which most of our readers are familiar. An operator must, he said, have no doubt as to the success or failure of his performance, a skiagram was useless as a control. Professor Lorenz then summarised his experience as to the length of time required for fixation after the operation; this varied so greatly with the age of the patient that no precise rules could be formulated. The result of the operation varied with the age of the patient, the most favourable ages being from the third to the fifth year, the seventh year was the limit at which a double dislocation could be successfully treated, and the ninth year was the limit for a unilateral dislocation.

Professor SALAZAR DE SOUZA (Lisbon) read a paper on

Orthopædic Surgery for Spastic and Paralytic Deformities of Nervous Origin.

He discussed cases met with after anterior poliomyelitis and Little's paralysis. In anterior poliomyelitis transplantation of tendons had not given so good results as similar operations for paralysis following trauma. This was explained by the fact that the so-called "healthy" muscles in a limb affected by anterior poliomyelitis were never or only rarely quite healthy. Ankylosis of the joints was more often indicated than transplantation of tendons. For spastic paralytic deformities the best methods were tenotomy, stretching of the tendons followed by over correction and fixation in plaster. Transplantation would be reserved for obstinate cases, due either to long duration or to exaggerated contractions accompanied by manifest atrophy of the antagonistic muscles. Then the steps to be taken were: (1) tenotomy of the contracted muscles; (2) permanent abolition of part of these muscles by means of (3) the transference of their energy to the antagonistic stretched muscles. In cases of spastic diplegia of cerebral origin the results were never good; the joints might require to be fixed and tenotomy performed so as to permit of the adjustment of some orthopædic apparatus.

Dr. P. REDARD (Paris) also read a paper on this subject. He considered first the paralytic deformities consequent on partial or total destruction of the nerve supply of the muscles of the limbs, in which the surgeon had to contend against both the paralysis and the deformity. At the present day the chief method was transplantation of tendons, and the lower extremities gave the greatest field for this form of surgery. The spastic deformities were next reviewed, and he pointed out the necessity of distinguishing between true contractures, with exaggerated reflexes, normal electrical reactions and disappearance under chloroform, and false or pseudo-contractures, with absent reflexes and persistence under chloroform. The principal surgical operations in vogue were considered under the headings: (*a*) forcible replacement; (*b*) operation on the tendons: (1) tenotomy, stretching, and shortening of tendons, (2) anastomosis of muscle and tendon by various methods of transplantation, (3) transplantation of the tendons into the periosteum, (4) transplantation with artificial tendons, and (5) tendinous fixation; operation on (*c*) the aponeuroses and muscles; (*d*) the capsules and ligaments; (*e*) the bones; (*f*) the joints; (*g*) the nerves; and (*h*) the skull and vertebræ. The value of these methods and their indications in paralytic and spastic deformities respectively were next considered at length and the conclusions were drawn that the tendinous transplantations and neurotomies were only of occasional use. Tenotomy was useful in spastic deformities such as Little's disease, spastic hemiplegia, and diplegia. Torticollis and facial spasm did better with psychotherapy. Where groups of muscles were paralysed transplantation was indicated. Nerve anastomosis and nerve suture were useful in traumatic cases, obstetrical paralysis, and sometimes in infantile paralysis.

M. P. HAUSHALTER (Nancy) and M. R. COLLIN (Nancy) communicated a paper on

The Classification and Pathology of the Spastic Affections of Infancy.

A brief summary was given of the opinions of the leading neurologists on the symptoms and clinical relationships of the various spastic affections of infancy—spastic infantile hemiplegia, spastic diplegia, monoplegia, athetosis, and the several forms of *congenital* spastic rigidity unaccompanied by paralysis. The term Little's disease was nowadays employed to indicate cases of spastic diplegia in prematurely born infants. The clinical causes, such as protracted labour or asphyxia at birth, shed no light on the classification of rigidity. In order to arrive at any reasonable solution of the problem it was necessary to study the anatomical conditions underlying all types. In order of frequency these were (1) cerebral atrophy and sclerosis; (2) meningo-encephalitis; (3) porencephalus; (4) hydrocephalus; (5) small convolutions; (6) cerebral softening; (7) histological alterations in the pyramidal tract without macroscopical lesions; and (8) lesions in the centre of the cord. A detailed analysis of the recorded cases from 1885 to 1904 was given and the conclusion was drawn that out of 56 cases on which a necropsy was performed, in 52 the lesion was in the brain and in two only was it in the spinal cord. Of the 52 cerebral lesions, in 51 cases the lesion was found in the anterior part of the brain and was mainly superficial, the central nuclei having been only rarely involved. With reference to spinal lesions Déjérine had made a careful study of two cases with sclerosis in the cervical region of the cord; his facts were of the utmost importance because they proved that the only essential factor in cases of spastic rigidity was a lesion involving the pyramidal tract in the spinal cord. Thus it had been demonstrated that in the two groups of causes—cerebral and spinal lesions—the common factor was an alteration of the pyramidal tract in the spinal cord. This pathological alteration might consist of destruction, more or less complete, defective formation, or absence of the tract. Arrested development of the pyramidal tract could not account for all the symptoms, however; if such were the case all infants born at seven months would have rigidity. The lesion was always in the upper motor neuron; the reflex arc with the motor cells in the anterior horn of the cord remained intact. The evolution of the theories relative to rigidity in general, and to infantile rigidity in particular, were then reviewed—the strychninism of Charcot, the theories arising from Adamkiewicz's idea of muscle tonus, the evidence of Jackson and Bastian as to the influence of the cerebellum (1896), and the careful observations of van Gehuchten and Déjerine. Grasset's theory of three stages of neurons (1899) explained more clinical facts than did that of any previous writer but up to the present no theory adequate to explain all cases of rigidity had been presented.

SURGERY.

Dr. **BARTHÉLEMY GUISY** (Athens) read a paper on

Chronic Urethritis and its Treatment.

He said that under the term chronic urethritis is included every chronic, painless inflammation of the mucous membrane of the urethra of gonococcal origin, even though no gonococci may be present. There are three main varieties: (1) those in which gonococci are still present; (2) those which are microbic but gonococci are absent; and (3) those in which no organisms are to be found. The spread of a gonococcal urethritis from the anterior to the posterior urethra and to the deeper structures is due partly to the active movements of the gonococci and partly to the movements of the leucocytes which have swallowed them. Within a few hours of infection of the urethra gonococci can be found in the submucous tissue and around the glands of the urethra. The reasons for a urethritis becoming chronic are: (1) the presence of some constitutional condition, such as general weakness or rheumatism; and (2) certain special anatomical conditions in the urethra, such as a stricture or an abscess. Dr. Guisy thinks that stricture of itself has very little to do with the production of a chronic urethritis. The most important cause is the gonococcal infection of the glands of Littré and the crypts of Morgagni, from which repeated reinfection of the urethra may proceed. The treatment of chronic gonococcal urethritis consists, in the first place, in its prevention by the abortive treatment of acute gonorrhœa with extensive lavage of the urethra with various antiseptic solutions. In a chronic urethritis, if examination shows gonococci still to be present, the same treatment should be adopted as if the inflammation were acute, any vegetations, abscesses, or other gross lesions having been previously removed. Cocainisation of the urethra is necessary before the lavage is commenced and very weak solutions of permanganate of potassium and of perchloride of mercury are the most useful. When success does not follow, some lesion, such as a granulation or polypus, must be sought for and removed. In cases of chronic urethritis in which some organism other than the gonococcus is present similar treatment should be adopted and even when no microbe is present lavage should be used. In all cases the only internal treatment should be the administration of urotropin and arheol after the local treatment has ceased.

Mr. **REGINALD HARRISON** (London) read a paper on

Surgical Interference in Medical Nephritis.

He said that tension in itself may do permanent harm to the kidney, as in acute inflammation and in chronic inflammation, also where the capsule is thickened and contracted. In some forms of renal inflammation therefore surgical interference may be useful and the indications are: (1) progressive signs of kidney deterioration, as shown by the persistence or increase of albumin when it should be disappearing from the urine; (2) actual or threatened suppression of urine; and (3) where a marked disturbance of the heart and circulatory system occurs in the course of inflammatory renal disorders. As to which kidney should be selected for operation it is not material unless pain is present on one side. Usually the relief of tension in one kidney aids the other. In one case where acute suppression of urine followed an operation for internal urethrotomy there was intense pain over one kidney. Mr. Harrison did a renal capsulotomy and this was followed by the restoration of the urinary secretion and recovery of the patient, though only three ounces of blood-stained urine had been excreted in the 54 hours intervening between the operation on the urethra and the division of the capsule of the kidney. The operation consists in the exposure of the kidney by a lumbar incision and in a linear incision through the capsule two or three inches long; a drainage tube is then inserted so as to remain in contact with the kidney and the wound is sutured and dressed.

Dr. **ALFRED POUSSON** (Bordeaux) read a paper on this subject and said that four operations have been suggested for acute nephritis—namely, nephrectomy, total or partial, nephrotomy, and decapsulation. Nephrotomy acts by relieving tension and by local bleeding. Decapsulation only reduces the compression of the kidney. The mortality of all forms of surgical interference is only 15·4 per cent. and the patients who have survived the operation have done well. This mortality justifies surgical intervention in acute nephritis, but only in severe cases which have failed to respond to medical treatment. Acute nephritis is often unilateral and the affected side can generally be diagnosed, especially by means of cystoscopy and separation of the urines of the two kidneys. In cases where both kidneys are affected the treatment of one often relieves the other. Nephrotomy is the operation of choice for acute nephritis. Nephrectomy should be reserved for cases where there are severe lesions limited to a single kidney. Decapsulation is much inferior to incision of the kidney. In chronic nephritis surgical intervention can do much but it should only be employed where medical treatment can do no more. Nephrotomy is less dangerous than decapsulation and it should be preferred. It is difficult to speak with certainty but decapsulation seems to be the only operation which gives a hope of a radical cure of chronic nephritis but it is best to combine with it a unilateral nephrotomy.

Dr. **FÉLIX LEGUEU** (Paris) read a paper on

The Surgical Treatment of Prostatic Hypertrophy.

He said that when the prostate is hypertrophied prostatectomy is the only operation which deserves consideration and it is specially indicated when the hypertrophy has caused chronic retention and regular catheterisation has become necessary. There are two operations, the perineal and the suprapubic; of these two the perineal route is less dangerous but it is not always successful, while the suprapubic method is more dangerous, but if the patient recovers he will be completely cured. Dr. Legueu certainly prefers the suprapubic method and he considers this method indicated in all cases where the prostate is large and projects into the bladder; the suprapubic operation is also preferable when the middle lobe is well marked; also in cases where the enlargement is definitely adenomatous and therefore the prostate can be enucleated. The condition of the patient must also be considered and the stronger and younger patients are more suited to the high operation. The perineal operation is indicated where much sepsis is present as the bladder is better drained.

Dr. **ALBERT FREUDENBERG** (Berlin), in his paper on this subject said that there is no method of treatment which is applicable to all cases of prostatic hypertrophy, though in turn several operations have been acclaimed as the best method. There is no doubt that vasectomy is the least dangerous but the results are very poor. On behalf of Bottini's operation it may be said that patients are more willing to undergo it and therefore it can often be done before infection of the urinary passages has occurred. It causes less interference than prostatectomy and can be carried out with local anæsthesia. Moreover, sexual power is not lost and there is no risk of a permanent urinary fistula. In favour of prostatectomy it may be said that it needs no special experience in urinary surgery or special instruments and that there is less risk of recurrence than in Bottini's operation. On the whole, Dr. Freudenberg considers that Bottini's operation is a milder operation than prostatectomy and therefore more suited for weak and elderly patients; it should also be used in young patients when it is desirable not to interfere with the sexual power. It is also suited for small and middle-sized prostates. Where it is not possible to gain an idea as to the size of the prostate before the operation the suprapubic method is preferable.

OPHTHALMOLOGY.

Secondary Cataract.

Professor N. MANOLESCU (Bucharest) read an interesting paper upon this subject before the section in which he dealt fully with the causes of secondary cataract, its different anatomical and pathological features, the operative procedures recommended with their prognosis, and the preventive courses that can be adopted. The causes are most commonly direct irritation, which prevents the absorption of lenticular fragments remaining after cataract extraction, and indirect irritation or infection from syphilis, tuberculosis, gout and albuminuria, or rheumatism. Operation for secondary cataract Professor Manolescu considered to be invariably a serious one and one that is followed in the experience of different operators by many complications, such as inflammation more or less grave of the corneal wound, of the iris, choroid, and ciliary processes, panophthalmia, sympathetic ophthalmia, and tertiary cataract. He proceeded to summarise briefly the procedures usually adopted by various authorities for avoiding these unfortunate sequelæ and considered that the preventive methods might be summarised under six heads: (1) the original extraction should be as complete as possible, only ripe cataracts being operated upon; (2) a large fragment of the anterior capsule should be removed; (3) appropriate measures must always be taken against infection, especially of the ciliary region; (4) the posterior capsule must be incised after the complete cessation of all post-operative irritation if the formation of secondary cataract is suspected; (5) where complete removal of all lenticular fragments has been impossible mydriatics should be used until their disappearance; and (6) all individual diatheses must be appropriately treated.

Intra-ocular Tuberculosis.

Mr. E. TREACHER COLLINS (London) read a report upon this subject based upon his own clinical and pathological experience, with quotations from the writings of others where these have been imperfect or incomplete. He said that he had collected 18 cases in which the eye had been excised for intra-ocular tuberculosis, the specimens of which were preserved in the Royal London Ophthalmic Hospital, and a tabular statement of the clinical and pathological details of these cases will be published in the official Transactions of the Congress. After briefly showing that intra-ocular tuberculosis had been recognised for at least 100 years and been diagnosed ophthalmoscopically for 50, Mr Collins pointed out that at the present time we possess three tests—the histological, the experimental, and the bacteriological—by which the tuberculous character of a growth in the eye can be determined. A new growth in the eye showing histologically the aggregation of cells, known as giant cell systems, and also areas of caseation, may be almost certainly pronounced tuberculous. Experimental tests by inoculation from eyes affected with tubercle give such uniform results that this method must be regarded as one of the most certain that we possess. Bacteriological tests are not so sure, for failure to find the specific bacillus in cases of undoubted tuberculosis of the eye has been a common experience among excellent observers and skilled microscopists. The bacilli in some cases are very limited in number and may easily escape detection. With regard to the modes of origin of intra ocular tuberculosis, Mr. Collins points out that there is much still to be debated. Several cases of exogenous infection of the conjunctiva with tubercle as the result of wounds have been recorded; there are cases reported of tuberculosis of the iris following perforated wounds; Greef has described a case of auto infection of the cornea, endogenous infection of the eye with tubercle in acute disseminated tuberculosis has been pointed out as occurring in the choroid by Cohnheim and less frequently in the iris; while there are cases in which tuberculosis appears in the eye without any previous sign of the disease in the body elsewhere. The origin of these cases is of considerable practical importance, as the treatment to be adopted may be largely influenced by the view taken as to the primary or secondary origin of the affection of the eye. Sex appears to have no predisposing influence and further evidence is required as to the frequency with which an injury precedes the condition before this can be accepted as a predisposing cause. The frequency with which intra-ocular tubercle occurs, with or without other clinical manifestations of tuberculosis, is not yet determined. Diagnosis is often very difficult, nor is it decided exactly what lesions of the choroid are to be regarded as tuberculous, but although most writers speak of intra ocular tuberculosis as a very rare disease there can be no doubt that the modern tendency is to recognise a much larger number of affections of the eye as falling within this category. The treatment is remedial or operative. Mr. Collins considered that in the light of the recent researches of Professor A. E. Wright on the opsonic power of the blood further investigation is required into the subject of the treatment of intra-ocular tubercle with tuberculin. As regards operative treatment the indications are not very simple. If the intra-ocular condition is primary enucleation would seem a reasonable course, but occasionally the tuberculous infection which previously had been confined to the eye, appears to become disseminated by operation. Again, it is not easy to say if the intra-ocular manifestation is primary, and if other infection is present it would manifestly be wrong to remove the eye while useful vision was retained in it and there were no symptoms of sympathetic ophthalmia.

THE GENERAL ASSEMBLY OF THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS.

(FROM OUR SPECIAL COMMISSIONER.)

Lisbon, April 18th.

THE MORNING SITTING.

To the International Association of the Medical Press appertains the honour of having inaugurated the great hall of the new School of Medicine. The first meeting held and the first speeches pronounced in this magnificent building were those of the representatives of medical journals of different European and South American nations. Here on the dais ascended, on the morning of April 17th, Señor Abel d'Andrade, the General Director of Public Instruction and professor of law at the University of Coimbra, who came to represent the Portuguese Government. By his side sat Dr. Carlos M. Cortezo, President of the International Association of the Medical Press; Dr. R. Blondel, the general secretary; and Professor Miguel Bombarda, general secretary of the Fifteenth International Congress of Medicine. The other members of the association sat on a double row of chairs that had been placed facing the platform.

Professor BOMBARDA opened the proceedings by expressing his satisfaction in welcoming to Portugal the representatives of the medical press of so many different countries. He said that being himself a journalist he had every reason to be sincere in such good wishes. He hailed with delight the representatives of what he believed was the most powerful lever in human society. In this he felt that he had the support of the whole population of Portugal, and though they were a small people they had large hearts. In the work of organising the medical press he hoped that the members present would realise that in the past they had been too exclusively professional. It was now urgently necessary to go beyond such narrow limits. They represented, in the first instance, the interests of medical men but these would be best served by considering the interests of civilisation as a whole. Their professional interests were to be discussed in association with those of the community at large. Certainly the first duty of the medical practitioner was to treat the sick but there was a still higher cause to serve. The profession must go beyond narrow professional limits and study its part, its function, its general relationship with the collectivity by which it was surrounded, the social life and the needs of society. In saying these words the thought of his venerated master came upon him; he remembered Virchow who had created social medicine. It was when he went to Silesia to study the terrible epidemic of typhus fever that Virchow founded a medical journal to defend the interests of the poor and the abandoned, the victims of hunger fever. He saw the great misery that then prevailed and understood how little medicine was of use in the face of starvation. After 30 years, during which time the medical press of Portugal had devoted itself almost exclusively to purely technical professional matters, they were to-day taking up the traditions of Virchow and giving a larger part in their columns to social medicine.

Dr. CARLOS M. CORTEZO followed, recalling the history of the association, how the idea germinated at Rome and gave rise to the Congress held at Paris in 1900, the meeting of the conference at Monaco, and the final constitution of the International Association at Madrid. The first act of the newly created body was an act of courtesy. They had nominated him as its president. He was pleased to have one more opportunity of expressing his gratitude for this compliment paid to Spain in his person. He was the more gratified that as president he had the joy of being able, in the name of the medical press of the whole world, to thank the Portuguese press and the Portuguese medical profession for all that they had done, and so well done. He hoped that in the present gathering they would have opportunities of proving their disinterestedness.

Dr. R. BLONDEL, as general secretary, was called upon as the next speaker. He rose, however, protesting that he was a worker and not a speaker. He only desired to make a business statement. He wished to explain that they were not more numerous because this was not a congress but a statutory meeting of the association. At Paris in 1900 it was necessary to study the general question and to try to found a society, so a congress was held with its doors open to all comers. Even then no further progress was accomplished than that of nominating a committee to draw up statutes. These had to be discussed and adopted by the conference of Monaco so as to be submitted for final approbation at the Madrid Congress. Now that the association was founded, there was no further need of congresses to found it. At a general assembly such as the present all members of the association might attend; as a matter of fact, however, most of the branches or different nationalities had contented themselves in sending their delegates. This proved the trust and confidence reposed in these delegates. There were some important matters on the agenda, and notably the publication of journals for advertisement purposes and their gratuitous distribution. In conclusion, he had to thank Professor Bombarda for his courtesy. He came all the way to Berne from Lisbon to discuss how matters could be organised for the best advantage of the press; this, too, at a time when he was already fully occupied organising the forthcoming International Congress of Medicine. As to the future, the part which the International Association of the Medical Press could play was enormous; its potentialities, however, would be all the greater, the great purpose to which Professor Bombarda alluded would be the more readily fulfilled, if, at first, they moved forward with prudence and circumspection.

Councillor ABEL D'ANDRADE, the General Director of Public Instruction, then rose and explained that he spoke in the name of the Portuguese Government. The Government was glad to inspire itself by the perusal of the medical press. It was the mission of the Government to translate into decrees and laws what the medical profession had proved to be necessary for the welfare of the commu In its series of conferences and congresses the press, fourth voice in the State, had striven to preserve knowle to disperse ignorance, and to convey equally to the co of the poor as to the mansion of the rich the light she the advance of science. The press had the highest rôle had not only to follow the discoveries of science b explain the causes of disease and to suggest the remed merely of such sickness but of those evil social and econ cal conditions which were the cause of disease. He expr the hope that the press would give to the Government force necessary to attempt the needed reforms.

The meeting then adjourned without the usual of speeches from the representatives of the diff nationalities.

A group of prominent members of the International Association of the Medical Press. The seven in the back row, reading from left to right, are—Professor Cornil (Paris); Professor Posner (Berlin), Councillor Abel d'Andrade, Director General of Public Instruction (representing the Portuguese Government); Dr Carlos M Cortezo (Madrid), former President of the International Association of the Medical Press; Professor Miguel Bombarda, General Secretary of the Fifteenth International Congress of Medicine; Dr. R. Blondel (Paris), General Secretary of the International Association of the Medical Press and Paris Correspondent of THE LANCET; and Dr. Alfredo Luiz Lopez, Treasurer of the Fifteenth International Congress of Medicine. The ten in the front row, reading from left to right, are:—Dr. Antonio de Azevedo, Assistant Secretary of the Fifteenth International Congress of Medicine; Mr. Adolphe Smith, THE LANCET; Mr. H. W. Armit, *British Medical Journal*; Dr Déjace (Belgium), *Le Scalpel*; Professor Daniel de Mattos of the University of Coimbra; Professor J. J. da Silva Amado (Lisbon), Dr. Azevedo Neves, Assistant Secretary of the Fifteenth International Congress of Medicine; Dr. Guevedo (Mexico) Editor of the *Escola de Medicina*; Dr. Bettenecourt Ferreira (Lisbon), *Journal of the Society of the Medical Sciences*; and Dr. Fisaç (Spain), *El Siglo Medico.*

THE AFTERNOON SITTING.

It was not before the afternoon meeting held on April that the real work began. Dr. CARLOS M. COR on taking the chair, at once called upon the general secretary, Dr. BLONDEL, to read the minutes of the last meeting of the International Committee. This, it will be remembered, was held at Berne on April 27th and 28th of last year. These minutes having been approved, proofs of the annual report were submitted and it was explained that each member of the association would receive a copy from his national secretary who would also have a few spare copies to be sold for one franc to anyone desiring the same. Dr. Blondel concluded by proposing that, as the Association of the Portuguese Medical Press now numbered 20 members, representing eight medical periodical publications, they should be entitled to two instead of one representative on the International Committee. This suggestion was readily accepted. Dr. Blondel then said that the first business was the election of the officers of the association and some conversation arose as to the unsatisfactory condition of affairs in regard to the assistant secretary and treasurer who had failed to apply to the affiliated associations for their subscriptions and was not in attendance on the present occasion. Explanations were given as to the heavy family bereavements and the precarious state of health of the treasurer.

Mr. ADOLPHE SMITH rose and argued that before the elections it was indispensable to come to a decision as to the proposal which it was his duty to make on behalf of the Association of the British Medical Press. It was their opinion that the present arrangement was not satisfactory and that it was desirable to modify the last clause of Article V., Chapter II., of the statutes of the International Association of the Medical Press adopted by the Conference of Monaco. Therefore he now proposed to abrogate completely the last paragraph of Article V. worded as follows:—

> The headquarters of the association is fixed at Brussels The assistant secretary and treasurer is alone obliged to reside in Belgium.

In the choice of their officers they must select those who were best able to render efficient service and this they might not be able to do if their choice was limited to one nationality.

Dr. DÉJACE (Belgium) did not oppose this proposal but he deeply deplored the fact that it had been thought necessary to make it. Formerly Belgium had been selected because it was neutral ground and geographically the most convenient place to meet.

Dr. BLONDEL pointed out that in practice half the proposal had been carried out. The last meeting of the committee was held at Berne and not at Brussels, this having been found more convenient.

Professor POSNER said that the British proposal amounted to legalising what in practice they had already been doing. There was no idea whatsoever of criticising the Belgians but they must be practical and win back their freedom of action. Rules were not eternal and should only be maintained so long as they proved useful, therefore the Germans and Austrians agreed to the proposal

Professor CORNIL supported Professor Posner and thought that the treasurership should be transferred to one of the nations that had rendered the most service—France, Germany, or Great Britain.

The motion abolishing the last paragraph of Article V. quoted above was then carried unanimously.

Mr. SMITH thereupon rose again and said that now that the motion had been carried he was most anxious to express his high appreciation of their close neighbours the Belgians and of the many eminent services which they had rendered to the advancement of science and progress. Doubtless in Belgium very competent treasurers could be found, notably Dr. Déjace himself, but they felt that they could scarcely ask another Belgian to accept the post in the circumstances, and therefore the difficulties would be easiest overcome by looking for help in this respect to some other nation.

These remarks were well received as all present were most anxious not in any way to hurt the feelings of their Belgian colleagues. Dr. DEJACE then rose and expressed his gratitude for the expressions of sympathy and friendship that had been uttered and the incident ended harmoniously.

The committee then proceeded to select its president. Professor Posner was elected by acclamation; nevertheless, and so as to avoid establishing a precedent which might prove awkward on other occasions when less unanimity might prevail, the committee proceeded to vote again and by secret ballot with precisely the same result. Professor Bombarda (Portugal), Dr. Déjace (Belgium), and Dr. Ascoli (Italy) were elected vice-presidents; Dr. R. Blondel (France), of course, was enthusiastically reappointed general secretary; and Dr. Dawson Williams (Great Britain) was elected as treasurer.

The next question was where the committee should meet in 1907. The British representatives invited the committee to meet in London just before the Second International Congress on School Hygiene which will hold its session from August 5th to 10th, 1907, in that metropolis. This proposal was accepted. It was also decided that the head office of the International Association of the Medical Press should be at the Bureau des Renseignements of the Paris Sorbonne. This gave Mr. Smith an opportunity of complimenting Dr. Blondel on his admirable organisation of the bureau and the services which it had already rendered to students and travellers from all countries. If the same success attended the organisation of the association of the medical press great would be the work accomplished.

Dr. BLONDEL replied that such success did not depend on him but on the nations affiliated. For instance, the Italians were quarrelling among themselves and had founded two rival national associations of the Italian medical press, with the result that neither of these bodies had sent representatives to the present meeting.

This concluded the work of the International Committee and the doors were then opened to any members of the association with the result that several Portuguese, Spanish, Mexican, and Brazilian members came into the room where the Committee had been sitting. Dr. Mendoza and Dr. Lara had papers to submit but were not present. The question of those journals that professed to be medical journals but were issued by manufacturers and distributed gratuitously so as to serve as advertisements for their wares was taken up for discussion.

Dr. BLONDEL inquired whether it would be possible to refuse the insertion in genuine medical journals of advertisements that appeared in these gratuitous prints.

Professor CORNIL remarked that these papers reproduced articles from legitimate papers. If they were promptly prosecuted for so doing such action would wreck such scissors-and-paste journalism.

Dr. DÉJACE maintained that if reproduction was theoretically forbidden, in practice the tribunals did not enforce the law. In any case the Berne Convention only protected the literary form, whereas in science it was the fact that had the chief value and the description of a new fact or theory could be reproduced anywhere if a somewhat different phraseology was employed.

Mr. H. W. ARMIT said that the Americans were the chief sinners so far as the English language was concerned and against them there was no possibility of legal action.

A motion was proposed by Professor CORNIL, seconded by Dr. BLONDEL, as follows:—

> As a commencement of the struggle against the invasion of gratuitous journalism the general assembly of the International Association of the Medical Press recommends that each journal belonging to the association should inscribe, on its first page, an announcement that the reproduction of the articles contained in the issue is forbidden to all medical journals that do not belong to the International Association of the Medical Press.

This was adopted.

The next question was termed "internal publicity"—namely, the growing demands made by advertisers for favourable notices in the body of the paper. The advertisers complain that their usual advertisements are torn out when the journals are bound up in a volume. Others say such notices deceive no one and are obviously advertisements. But now, Dr. Blondel urged, there was an ever-increasing demand for articles written in such a manner that they would deceive. Scientific books were sent with the request that they should be reviewed and if this was not done the advertisements were withdrawn. Some check must be put on these growing exigencies.

Professor POSNER urged the difficulty of drawing the line between genuine scientific articles and equally scientific articles that might be construed as advertisements. The more important papers refused to analyse over and over again the same products. But some of the manufacturers had laboratories and highly scientific men in their employ where work was done which was quite equal to that of a university or a faculty. So the matter would always remain a question of the value of the individual author and of the article. There was, he feared, no other solution than that which depended on the competence of the editor. It was above all necessary to prevent the editor from being influenced by the publisher.

After a considerable amount of conversation on this subject it was ultimately decided that a report should be prepared for the next meeting and the assembly then adjourned till the morrow.

(To be continued.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8332 births and 5250 deaths were registered in the week ending April 21st. The annual rate of mortality in these towns, which had been equal to 17·0 and 17·1 per 1000 in the two preceding weeks, further rose last week to 17 3. In London the rate was 19·2 per 1000, whereas the mean rate in the 75 other large towns did not exceed 16 5. The lowest death-rates in these towns during the week were 6 9 in Bournemouth, 7·8 in Wolverhampton, 9·3 in Southampton, and 9·6 in Tottenham; the rates in the other towns ranged upwards to 23·1 in Tynemouth, 23·2 in Coventry, 23·4 in Middlesbrough, 23·6 in Liverpool, and 25 9 in Bromley. The 5250 deaths in the 76 towns included 519 which were referred to the principal infectious diseases, against 457 and 518 in the two preceding weeks; of these, 214 resulted from measles, 133 from whooping-cough, 58 from diphtheria, 48 from diarrhœa, 47 from scarlet fever, 18 from "fever" (principally enteric), and one from small-pox. The deaths from these diseases were equal to an annual rate of 1·7 per 1000 in the 76 towns and to 1·9 in London. No death from any of these infectious diseases was registered last week in Hastings, Brighton, Bournemouth, Southampton, Reading, or in eight other large towns; while they caused the highest death-rates in Bradford, Bristol, Preston, Liverpool, Walthamstow, and Burnley. The highest death-rates from measles during the week occurred in Liverpool, Preston, Walthamstow, and Burnley; from whooping-cough in Bristol, Aston Manor, Merthyr Tydfil, West Bromwich, Burnley, and Coventry; from diphtheria in Walthamstow and Halifax; and from diarrhœa in Warrington. The highest death rates from scarlet fever occurred in Middlesbrough and Sheffield. "Fever" showed no marked fatality in any of the large towns, and one fatal case of small-pox occurred in Plymouth. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals were still seven at the end of last week, one new case having been admitted during the week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday, April 21st, was 2225, showing a further decline from numbers decreasing steadily from 2628 to 2301 in the six preceding weeks; 288 new cases were, however, admitted during the week under notice, against 270 in the previous week. The deaths referred in London to pneumonia and other diseases of the respiratory organs, which had been 332 and 357 in the two preceding weeks, further rose last week to 399 and exceeded by 104 the corrected average for the corresponding week in the four preceding years, 1902–05. The causes of 51, or rather less than 1 per cent, of the deaths registered during the week in the 76 large towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Bradford, Hull, Newcastle-upon-Tyne, and in 48 other large towns; whereas the proportion of uncertified deaths showed a considerable excess in Birmingham, Coventry, Liverpool, Sheffield, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19 4 and 19·1 in the two preceding weeks, further declined to 17·6 during the week ending April 21st, but exceeded by 0·3 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·6 and 13·1 in Perth and Aberdeen to 18·5 in Glasgow, 19·6 in Dundee, and 20·6 in Greenock. The 634 deaths in these eight towns included 15 which were referred to measles, 14 to whooping-cough, 12 to diarrhœa, seven to diphtheria, four to "fever," one to scarlet fever, but not one to small-pox. In all, 53 deaths resulted from these principal infectious diseases during the week, against 51 and 64 in the two preceding weeks. These 53 deaths were equal to an annual rate of 1·5 per 1000, which was 0·2 below the mean rate during the week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 27, 20, and 23 in the three preceding weeks, declined last week to 15, of which eight occurred in Glasgow, three in Edinburgh, and two in Dundee. Of the 14 deaths from whooping-cough, which exceeded by two the number returned in each of the two previous weeks, ten were recorded in Glasgow. The deaths referred to diarrhœa, which had been 15 and 11 in the two previous weeks, were 12 last week, and included five in Glasgow and three in Edinburgh. Four of the seven fatal cases of diphtheria occurred in Glasgow, as did three of the four deaths referred to fever, which included two attributed to cerebro-spinal fever. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 142 and 170 in the two previous weeks, declined last week to 140, but exceeded by 14 the number referred to these diseases in the corresponding week of last year. The causes of 13, or rather more than 2 per cent., of the deaths registered in the eight towns during the week were not certified, the proportion of uncertified deaths in the 76 English towns being less than 1 per cent.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·1, 21·1, and 23 4 per 1000 in the three preceding weeks, further rose to 28·1 during the week ending April 21st. During the 13 weeks of last quarter the death-rate in the city averaged 22·9 per 1000, against 16 6 and 17 4 in London and Edinburgh; and during the first three weeks of the current quarter the Dublin death-rate has further increased of 24·2. The 204 deaths of persons belonging to Dublin registered during the week under notice showed an increase of 26 upon the number returned in the previous week, and included six which were referred to the principal infectious diseases, against four and six in the two preceding weeks; of these, three resulted from measles, two from "fever," one from diarrhœa, and not one either from small-pox, scarlet fever, diphtheria, or whooping-cough. These six deaths from the principal infectious diseases were equal to an annual rate of but 0·8 per 1000, while the rate last week from the same diseases were equal to 1·9 in London and 1·4 in Edinburgh. The three fatal cases of measles showed an increase upon the numbers in recent weeks, as did the two deaths referred to "fever," probably enteric. The 204 deaths included 25 of infants under one year of age and 78 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a marked increase upon the numbers in the two previous weeks. Nine inquest cases and four deaths from violence were registered; and 87, or 43 per cent, of the 204 deaths were recorded in public institutions. The causes of six, or 3 per cent., of the deaths registered during the week were not certified, either by a registered medical practitioner or by a coroner.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: E. Sutton to the *St. George*, on recommissioning, and E. S. Tuck to the *President*, for three months' course at Guy's Hospital. Surgeons: F. L. de Verteuil to the *Hogue*, on completing; N. H. Mummery to the *Latona*; J. Verdon to the *Hyacinth* and M. T. Male to the *Russell*, both on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Percy Farrant, from the Seconded List, to be Lieutenant (dated April 1st, 1906).

The following have been appointed medical officers, London Recruiting Area: Lieutenant-Colonel H. Scott, retired pay, and Lieutenant-Colonel R. H. Hall. Captain A. C. Lupton, from Newcastle-on-Tyne, has been appointed to the 1st Life Guards. Lieutenant L. Bousfield has been selected for employment with the Egyptian Army.

THE ROYAL ARMY MEDICAL (MILITIA) CORPS.

The Army Council has decided that it is necessary to encourage the non-commissioned officers and men of the Royal Army Medical (Militia) Corps to qualify as cooks, both for hospital and general purposes, and has directed that a sufficient number shall be trained at selected military hospitals to maintain an establishment of two cooks per company, the period of instruction being three months.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Northumberland Fusiliers: Surgeon-Major J. P. Elliot is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated April 11th, 1906); Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel J. P. Elliot resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated April 11th, 1906). 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry: Surgeon-Major A Macphee to be Surgeon-Lieutenant Colonel (dated April 11th, 1906).

THE KING'S BIRTHDAY.

Notice is given in the *London Gazette* that the King's Birthday will be celebrated in London and at all Home Stations on Friday, June 29th next. At all other stations His Majesty's Birthday will be celebrated on Friday, Nov. 9th next.

PATRIOTISM AT THE UNIVERSITIES

In the April number of the *University Review* Sir William Ramsay has written an article entitled "Patriotism at the Universities." It is an earnest plea for a scheme whereby men while at the university should be able to undertake to fit themselves for service in defence of their country. He reminds his readers that in Germany those who have passed the "Abiturientenexamen" of the high schools (gymnasia or oberrealschulen), which is equivalent to matriculation at our universities, are allowed not only to limit their time of service to one year but it is made easy for them to serve during one of their years of study. Their hours of compulsory drill are made to fit their hours of study. And further, he asks, "Could we not form the habit of devoting one of our university years to shooting and drill?" We see that the editor of the *University Review* invites discussion upon this important suggestion and we await the result of the discussion with interest. For nearly 900 years no foreign invader has set foot on English soil and possibly we have become lulled into a false security. It may be true that the British people will never agree to universal military service but surely it is not too much to ask that every able bodied man should, say between the ages of 18 and 25 years, give up one year of his time to learning to shoot straight and to perform simple military evolutions. One of the greatest strategists of the last century said that it was perfectly easy to get an army into England but almost impossible to get it out again If Sir William Ramsay's scheme were adopted other classes than those who go to the universities would probably follow suit and in that case an invader would probably never penetrate far into the country even if he succeeded in landing

THE ROYAL NAVAL HOSPITAL, STONEHOUSE, PLYMOUTH.

Lord Tweedmouth and the other Lords of the Admiralty made a visit of inspection to the Royal Naval Hospital, Stonehouse, on April 10th. They were received by Inspector-General J. C. B Maclean, Deputy-Inspector-General L. H. Kellett, and Deputy-Inspector General C. James. Fleet-Surgeon W. Eames, Staff Surgeon M. L B Rodd, and several other officers were also present. Lord Tweedmouth visited the medical and surgical wards. The sick officers' quarters were seen and also the improved blocks of buildings, which have been practically rebuilt, with their annexes and sanitary arrangements. Lord Tweedmouth, who remained a considerable time in the hospital, was much pleased with his inspection

ROYAL ARMY MEDICAL CORPS FUND

The *Army and Navy Gazette* states that the fourth general meeting of subscribers to the Royal Army Medical Corps Fund will be held in the theatre of the Royal United Service Institution on Monday, June 18th, at 3 P.M. The Director-General will preside. It is hoped that officers will freely express their views on any points connected with the fund which they may wish discussed. Those officers who wish for information on any special point are asked to communicate with the honorary secretary, Lieutenant-Colonel B. M. Skinner, at 63, Victoria street, London, S W., in order that facts and figures may be furnished in response to any question asked.

THE TEETH OF ARMY RECRUITS.

In future the teeth of army recruits will be tested not from the standpoint of a campaign like that in South Africa but from the general average conditions of European warfare.

SPANISH MILITARY HYGIENE.

Dr. E. Alonso G. Sierra, a Spanish military surgeon, writing in the *Revista de Sanidad Militar*, deplores the great want of cleanliness in the army. The soldiers scarcely ever take a bath or brush their teeth, and are not accustomed to wash their hands before their meals, added to which there is a most deplorable want of cubic space in the barrack-rooms. Were these matters rectified and a more liberal supply of easily assimilable proteids allowed in their rations he thinks that the present high mortality would be decreased by something like 95 per cent.

Correspondence.

"Audi alteram partem."

ANTERIOR OR POSTERIOR GASTRO-JEJUNOSTOMY?

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 14th, p. 1071, Mr. B. G. A. Moynihan maintains that I replied to, but did not answer, the arguments and criticisms in his former letter. This is a matter of opinion which I leave to the judgment of your readers. With your permission I will endeavour to reply to the arguments which Mr. Moynihan now puts forward. In his first paragraph Mr. Moynihan evades my point that the no loop operation has not been practised long enough to warrant a definite decision as to its value. He next remarks that "the operation of gastro-jejunostomy, if one may judge from published reports, is not so frequently performed in London as elsewhere." *Possibly* we are behind the times, although I think that published reports are not a trustworthy indication of the volume of work done, inasmuch as surgeons in London, whether from pressure of work or from disinclination, are very sparing as to the reports of cases which they publish. The great bulk of the cases are buried in the oblivion of hospital notes. Mr. Moynihan tells me that if I will look further afield I shall discover that the posterior operation with no loop is really the operation usually performed. I can only say that a careful search through the literature of the subject leads me to an opposite conclusion. In preparing my lectures I communicated with surgeons all over the country and I gathered from my inquiries that the no-loop operation is not commonly employed.

As regards Dr. Mumford's case, it is quite true that it was an instance of an anomaly of the duodenum, in that the fixed portion of the duodenum ended on the right side of the spinal column instead of on the left. This, however, I submit, does not affect the conclusion to be drawn from the record. The case is, as Mr. Moynihan admits, an argument against the no-loop operation. It illustrates the danger of fixing the jejunum to the stomach without the play afforded by a loop As Dr. Mumford remarks, "The play allowed to the movable stomach and jejunum was limited by the short radius—the ligament of Treitz to the anastomotic opening—afforded by the three-inch limb of jejunum." In other words, the no-loop operation is mechanically incorrect. Mr. Moynihan maintains that the condition found would have vitiated an anterior probably as much as a posterior operation. Even that fertility of imagination with which Mr. Moynihan kindly credits me does not enable me to conceive how, with the play afforded by the 12-inch loop of an anterior operation, the colon could be constricted, especially as in this particular case the stomach appears to have contracted in a lateral rather than in a vertical direction.

I am surprised to learn that Mr. Moynihan has adopted the method of stitching for two and a half years, for I find from his published records that one of his cases of gastro-jejunostomy performed in December, 1903, was operated on subsequently for an internal hernia through the aperture in the mesocolon. As gastro-jejunostomy in this case was performed less than two and a half years ago, I suppose that Mr. Moynihan must have stitched the jejunum to the mesocolon, and yet a hernia followed. I have no doubt that the method advocated by Mr. Moynihan is effectual so far as the immediate prevention of hernia is concerned, but I think we require further evidence that in every case the opening remains permanently closed. All surgeons are familiar with the readiness with which intestinal and omental adhesions become stretched. Surely such an event is possible when a structure like the mesocolon is stitched to contractile viscera such as the stomach or jejunum?

As regards regurgitant vomiting Mr. Moynihan maintains that the proximal jejunal limb becomes waterlogged. Mr. Moynihan, I admit, did say this in his first letter but I was loath to do him the injustice of believing that he really meant that waterlogging was the primary factor. Is there a particle of evidence that a healthy piece of intestine can become waterlogged apart from mechanical obstruction or paralytic distension? The whole of the small intestine is a series of loops. Do these loops ever become waterlogged apart from the conditions mentioned? I have witnessed a considerable number of necropsies on patients who have died from regurgitant vomiting and in every instance the waterlogging was clearly secondary to definite mechanical obstruction at the efferent opening. This is an observed fact; the hypothesis that waterlogging occurs as a primary condition is an ingenious speculation.

As regards peptic jejunal ulcer, I think my original contention is a perfectly fair one. I collected 19 instances, in 14 of which the anterior operation was performed, in two the posterior, in one Roux's operation, while in two the method was not stated. In the statistics given by Mr. Moynihan the disproportion is not so great, 17 instances following the anterior and six the posterior operation. I omit the cases in which an entero-anastomosis was performed, as I think it must be conceded that when this procedure is carried out peptic ulcer is more likely to occur, for the jejunal mucous membrane is exposed to the acid gastric juice unprotected by the presence of bile. In all the cases I collected gastro-jejunostomy had been performed prior to 1903. As jejunal ulcer is a comparatively remote sequel of gastro-jejunostomy, probably in all the cases yet recorded the operation had been performed not later than 1904. The point, therefore, is not whether the posterior operation is performed more frequently than the anterior at the present time (as I have no doubt it is), but whether such was the case during the period covered by the operations followed by peptic jejunal ulcer. I maintain that, so far as can be ascertained, during that period the anterior operation was more frequently performed and this circumstance is a reasonable explanation of the greater number of peptic jejunal ulcers which have followed the anterior operation. As regards the influence of a low opening on the production of jejunal ulcer I hardly think that the difference between the eight-inch loop of the posterior and the 12-inch loop of the anterior operation is a satisfactory explanation of the disproportion of cases which have followed the two methods. Mr. Moynihan disregards my contention that jejunal ulcer following the anterior appears to be a less serious complication than when it follows the posterior operation. Mr. Moynihan refers to the first gastro-jejunostomies which he ever saw, all done by the anterior method, and he tells us that of these cases there was one superb result, and a ghastly list of failures. In his first letter Mr. Moynihan referred to the complications which followed the posterior operation before the technique had been fully developed. Surely the technique of the anterior operation has been developed also, so that it is scarcely fair to instance the results of the earlier anterior operations as a criterion of what can be accomplished to-day. Mr. Moynihan asks, "Is there a surgeon in any part of the world who can bring forward any large number of cases of the anterior operation which will compare in results, immediate or remote, with those recorded by the Mayos, Mayo Robson, Hartmann, myself, or others?" Let me quote Dr. W. J. Mayo's (an advocate, be it said, of the posterior operation) statistics of anterior gastro jejunostomy. This surgeon and Dr. C. H. Mayo have recorded 421 cases of gastro-jejunostomy for benign and malignant disease. Of these cases 126 were anterior and 295 posterior. "The mortality," remarks Dr. Mayo, "in the anterior group was somewhat over 1 per cent. higher than in the posterior *but the percentage of secondary operations was greater after the posterior operation.* The mortality comparison is, however, hardly fair to the anterior method, as this group comprises a larger number of the earlier operations in which inexperience can be blamed for some of the misfortunes."

I trust that I do not turn a deaf ear to the evidence before me but I do believe that my senses enable me to distinguish between evidence and assertion, and I repeat that as yet I have not found any conclusive evidence to show that the results, either immediate or remote, are better after the posterior than after the anterior operation. If such evidence be forthcoming Mr. Moynihan need have no fear but that I shall act in accordance with it. Mr. Moynihan has obtained admirable results from the posterior operation. In my own smaller experience the results of the anterior operation have been excellent. I am confident that were Mr. Moynihan now to adopt the anterior method the results in his skilled hands would not be a whit inferior to those he has obtained from the posterior method in the past.

I am, Sirs, yours faithfully,
HERBERT J. PATERSON.

Upper Wimpole-street, W., April 23rd, 1906.

PS.—In THE LANCET of March 10th, p. 705, Dr. E. Cautley comments on some of the statements I made on the subject of infantile hypertrophic stenosis of the pylorus in my recent Hunterian lectures. Dr. Cautley points out that "statistical results of operations for this condition are of little value." With this remark I fully concur; indeed, in my lecture I expressed a similar view in the following words: "So much turns on the *condition of the infant* that it is impossible to estimate the relative mortality of these different procedures and it is probably on this factor and on the skill of the operator rather than on the particular operation adopted that the immediate result depends." Dr. Cautley thinks that I am inclined to give undue credence to reports of cases cured without recourse to operation. Doubtless some of the reported cures have been instances of mistaken diagnosis but I venture to think that the names of the physicians under whose care were the patients are sufficient evidence that the cases I quoted do not come under this category. Dr. Cautley is apprehensive lest my observations tend to make physicians procrastinate unduly. I trust no such evil result will ensue; such, at least, was not my intention. If, however, clinicians' diagnosis is as uncertain as Dr. Cautley suggests, procrastination may be in the interest of the patients, otherwise I fear that Dr. Cautley's insistence on early surgical treatment may lead to unnecessary operations on patients erroneously *supposed* to be suffering from this disease.

IN PRAISE OF RUM AND MILK.

To the Editors of THE LANCET.

SIRS,—I am pleased to see that Dr. Francis T. Bond, in THE LANCET of April 21st, p. 1135, draws attention to the great value of this combination as what one might term a food tonic, and I am particularly pleased to see that he uses the term Jamaica rum, for between Jamaica rum and the rum which is too frequently sold (Demerara rum) there is a very wide difference indeed. I had occasion some two years ago to investigate this question of the difference in quality between Jamaica and Demerara rum, and also to investigate the therapeutic action of good rum itself. I found that Demerara rum contained a little over 60 parts of combined ethers per 100,000 parts of absolute alcohol, whereas Jamaica rum contained anything from 300 to 600 parts of compound ethers in the same amount of absolute alcohol.

I went to considerable trouble to look up old authorities on the question of the therapeutics of rum and I was somewhat astonished to find them speaking so highly of this particular spirit. It was stated by one of these authorities that rum had a more decided action than either brandy, whisky, or gin in increasing the amount of carbonic acid given off from the system. It was further stated that rum was the only alcoholic liquor which produced perspiration, and, finally, the important statement was made that rum was one of the very best alcoholic restoratives, its action being not a mere flash-in-the-pan but of a steady and conservative character. Dr. Edward Smith, Dr. James Inman, Dr. Letheby, and Dr. Ringer all agreed upon this point. The first named stated that "the old-fashioned combination of rum and milk is the most powerful restorative with which he is acquainted." Dr. James Inman stated that "for internal use in cases of phthisis and similar diseases rum and milk is far better as a means of supplying fat to the body than cod liver oil." I have tested the remedy myself in a number of cases and I can personally vouch for the truth of the matter but I repeat the greatest care should be taken to obtain Jamaica rum and not Demerara rum.—I am, Sirs, yours faithfully,

MEREDITH YOUNG, M.D. Edin.

Stockport, April 23rd, 1906.

THE ARMY MEDICAL RESERVE.

To the Editors of THE LANCET.

SIRS,—The important question of first finding the necessary material to form such a corps is clearly put by your correspondent, "War Dog," in THE LANCET of April 21st, p. 1136. There are many who, I think, will agree with me that too much is made of military training in medical matters. Surgery and medicine are essentially the same, whether practised in the navy, army, or civil life, with the exception that in the latter a wider field is essential. The skeleton of a certain necessary administration is fully provided by the Royal Army Medical Corps. The civil surgeon, on the whole, is generally admitted to have proved a complete success. Any friction which did take place, in the future will probably disappear under the vastly improving conditions of the *personnel* of the standing corps. Should another war take place there must of necessity be a further call upon the profession with the result of an equally satisfactory response. The idea of specially training a body of such men surely is unnecessary. As to a reserve of men like myself, who have seen service under all conditions at the front and in hospitals, most of us are now settled in some way or other, and I think I may say that we are not looking for further trouble unless the country cannot do without us. Carry a large water-bottle and a packet or so of common cigarettes: these are the first requirements of a wounded soldier. I have always found the officers of the Royal Army Medical Corps willing and anxious to give at short notice any special instruction which might be required. I am, Sirs, yours faithfully,

J. L. AYMARD,
Late Civil Surgeon, 7th Dragoon Guards.

Wimpole-street, W., April 21st, 1906.

To the Editors of THE LANCET.

SIRS,—The idea of enrolling into a medical reserve the larger number of civil surgeons who were attached to the army during the late war is a scheme which one would have thought should have suggested itself to the authorities long ago; moreover, the confidential reports possessed would have enabled a pick to be made of the many they have to choose from, to say nothing of the advantages of practical experience possessed by these men gained in actual warfare, an experience which no training could ever give to the new men. That such a scheme has presented itself to the authorities may be taken for granted and it may be of interest to ask why it has not been adopted. It will doubtless be fresh in our memories the snub which the War Office received during the course of the war to its offers of commissions in the Royal Army Medical Corps offered to the civil surgeons; it is not likely they would care to receive a second. Again, if the authorities as it seems fear a refusal to enrol from experienced men one is naturally lead to ask if the reason for such refusal is probably due to a "knowledge of good and evil" which is possessed by the civil surgeons of the real state of matters in the Royal Army Medical Corps. Hence the reason for asking young men to enlist in a reserve of a service they have no experience of the shortcomings of. A civil surgeon who has once served knows that if he joined he would be entering a service possessed of many attractions of a social and gay life, but would invariably recognise that during his term of service he would lose ground in things medical and surgical. His time of training would be spent learning military routine, administrative duties, and compiling red tape returns, but that he would gain anything in medical or surgical work he knows would be almost impossible. If, on the other hand, all administrative work—returns of sick, payment of men, checking of hospital supplies, balancing of accounts, and the other multitudinous duties which at present fill in the greater part of medical officers' time—were carried out by military officers who have passed into the reserve or have been enrolled specially, as is the case in the army pay department, the civil surgeon would then feel more inclined to join a service in which he could conscientiously bring to bear with value and interest the experience which his practice has taught him. Until some scheme is adopted by the Royal Army Medical Corps of removing clerical duties to lay shoulders so long will the corps fail to fulfil its full duties to itself and to the nation.

I am, Sirs, yours faithfully,

THE AUTHOR OF THE "ARMY MEDICAL SYSTEM," &C.

CANCER GENESIS: TYROSIN AS A PROBABLE CAUSE OF LEUCOCYTOSIS IN CANCER.

To the Editors of THE LANCET.

SIRS,—I have noticed that under certain conditions it is possible to obtain what appears to be pure crystals of tyrosin from the juice of cancer cells and chemical experiments appear to support strongly the presence of tyrosin as Hoffmann's and Piria's reactions can be elicited. The importance of the presence of tyrosin in cancer becomes at once apparent when inquired into from the bio-physiological chemical standpoint of the initiation or cause of carcinoma and the subsequent course of the disease from a histological and clinical aspect. Tyrosin is paraoxyphenyl-α-amido-propionic acid and is the result of the prolonged action of pancreatic secretion on proteid matter. Tyrosin can be readily prepared from horn shavings by the action of sulphuric acid. Horn is an epithelial structure and the presence of tyrosin in epithelial cancer—particularly in epithelioma and mammary cancer—is not so extraordinary as it would seem. If tyrosin be decomposed we get various compounds, amongst which are paraoxyphenyl-propionic acid and β-phenyl-propionic acid. The former is hydroparacumaric acid and the latter is hydrocinnamic acid.

It is an accepted fact that the subcutaneous injection of either cumaric acid or cinnamic acid causes a well-marked leucocytosis.[1] During digestion, especially towards the end of the process in the small intestine, there is a marked leucocytosis normally taking place in the walls of the intestine and its villi. Is it not possible that the presence of tyrosin serves the purpose, amongst others, of calling up this leucocytosis, which is usually accepted as part of the method of fat absorption from the intestine, another of the results of pancreatic functions?

We here would appear to have a possible explanation of the non-inflammatory presence of leucocytes in the growing margin of a cancer and also a reason in support of my contention that the initiation of the cancer process is due to leucocytic action,[2] inasmuch as, owing perhaps to aging or faulty chemical action, epithelial cells may attract leucocytes by reason of the presence of accumulated tyrosin within or about the cells. Another most important matter bearing on the above is the fact that lately in all cases of cancer, wherever it may occur in the body, it has been stated that the mucous membrane of the stomach ceases to secrete hydrochloric acid and abundance of lactic acid is found to take its place. Now lactic acid is hydroxy-propionic acid and this fact at once points to an apparent connexion with tyrosin, which is a propionic derivative in combination with phenol, elsewhere in the body in cancer cases.

It would appear that one of two things is taking place: (1) that the stomach is trying to rid the system of the propionic radicle in an allotropic form; or (2) that the propionic radicle is being attached to a phenol radicle in the intestine and is being taken up in excess from the intestine and therefore appears in the tissues more or less free. The presence then of tyrosin in cancer tissue, especially in view of the alleged favourable action of trypsin on cancer, would appear quite compatible with the contention that the fundamental cause of cancer would probably be found to be some chemical disturbance in cell metabolism, directly or indirectly. Apart from the propionic-kresol compounds, there would appear to be also a chinolin compound allied to kynurenic acid present, as crystals which appear to be chinolinic in form have also been seen.

The above is a short *résumé* of the matter so far as I have worked at the subject at present, and further work on these lines aimed at increasing or diminishing tyrosin in cancer tissue ought to prove interesting and profitable in mesocolon, and yet a hernia followed. I have no doubt that the method advocated by Mr. Moynihan is effectual so far as the immediate prevention of hernia is concerned, but I think we require further evidence that in every case the opening remains permanently closed. All surgeons are familiar with the readiness with which intestinal and omental adhesions become stretched. Surely such an event is possible when a structure like the mesocolon is stitched to contractile viscera such as the stomach or jejunum?

CANCER GENESIS: TYROSIN AS A PROBABLE CAUSE OF LEUCOCYTOSIS IN CANCER.

To the Editors of THE LANCET.

SIRS,—I have noticed that under certain conditions it is possible to obtain what appears to be pure crystals of tyrosin from the juice of cancer cells and chemical experiments appear to support strongly the presence of tyrosin as Hoffmann's and Piria's reactions can be elicited. The importance of the presence of tyrosin in cancer becomes at once apparent when inquired into from the bio-physiological chemical standpoint of the initiation or cause of carcinoma and the subsequent course of the disease from a histological and clinical aspect. Tyrosin is paraoxyphenyl-α-amido-propionic acid and is the result of the prolonged action of pancreatic secretion on proteid matter. Tyrosin can be readily prepared from horn shavings by the action of sulphuric acid. Horn is an epithelial structure and the presence of tyrosin in epithelial cancer—particularly in epithelioma and mammary cancer—is not so extraordinary as it would seem. If tyrosin be decomposed we get various compounds, amongst which are paraoxyphenyl-propionic acid and β-phenyl-propionic acid. The former is hydroparacumaric acid and the latter is hydrocinnamic acid.

It is an accepted fact that the subcutaneous injection of either cumaric acid or cinnamic acid causes a well-marked leucocytosis.[1] During digestion, especially towards the end of the process in the small intestine, there is a marked leucocytosis normally taking place in the walls of the intestine and its villi. Is it not possible that the presence of tyrosin serves the purpose, amongst others, of calling up this leucocytosis, which is usually accepted as part of the method of fat absorption from the intestine, another of the results of pancreatic functions?

We here would appear to have a possible explanation of the non-inflammatory presence of leucocytes in the growing margin of a cancer and also a reason in support of my contention that the initiation of the cancer process is due to leucocytic action,[2] inasmuch as, owing perhaps to aging or faulty chemical action, epithelial cells may attract leucocytes by reason of the presence of accumulated tyrosin within or about the cells. Another most important matter bearing on the above is the fact that lately in all cases of cancer, wherever it may occur in the body, it has been stated that the mucous membrane of the stomach ceases to secrete hydrochloric acid and abundance of lactic acid is *found to* take its place. Now lactic acid is hydroxy-propionic acid and this fact at once points to an apparent connexion with tyrosin, which is a propionic derivative in combination with phenol, elsewhere in the body in cancer cases.

It would appear that one of two things is taking place: (1) that the stomach is trying to rid the system of the propionic radicle in an allotropic form; or (2) that the propionic radicle is being attached to a phenol radicle in the intestine and is being taken up in excess from the intestine and therefore appears in the tissues more or less free. The presence then of tyrosin in cancer tissue, especially in view of the alleged favourable action of trypsin on cancer, would appear quite compatible with the contention that the fundamental cause of cancer would probably be found to be some chemical disturbance in cell metabolism, directly or indirectly. Apart from the propionic-kresol compounds, there would appear to be also a chinolin compound allied to kynurenic acid present, as crystals which appear to be chinolinic in form have also been seen.

The above is a short *résumé* of the matter so far as I have worked at the subject at present, and further work on these lines aimed at increasing or diminishing tyrosin in cancer tissue ought to prove interesting and profitable in view of the latest experiments in cancer treatment and pathology. I am, Sirs, yours faithfully,

A LIFE OF "ECLIPSE."

To the Editors of THE LANCET.

SIRS,—May we ask the assistance of your valuable columns to let the fact be known that the first complete life of "Eclipse" is in course of preparation and that any reference to this celebrated horse in contemporary literature, to his breeder, the Duke of Cumberland, to his purchaser, Wildman, and to his subsequent owner, Dennis O'Kelly, will be very much appreciated. Many facts have already come to light from private and unexpected sources which have enabled us to settle various questions hitherto doubtful, such as the birthplace, the burial place, the authentic skeleton, and so forth. Many more letters, documents, prints, or paintings must still exist—besides those already brought to our notice by the generosity of their possessors—which will be of the greatest value. The monograph will be as completely illustrated as possible, from contemporary paintings and engravings and other sources, and will contain detailed photographs of the anatomy of Eclipse and the most famous of his descendants, which should prove interesting both to biologists and breeders. A sketch of racing in the days when Eclipse was on the turf will be included, with biographies of his breeder, owners, and others connected with the sport of that time. It is important that information should reach us before June 1st if possible and all letters, manuscripts, prints, or pictures, addressed to "Eclipse," care of Mr. W. Heinemann, 21, Bedford-street, London, W.C., will be acknowledged before that date and will be received not only with the greatest care but with profound gratitude. Any originals reproduced will be scrupulously guarded from injury and safely returned and may be insured if necessary while out of their owner's hands if a separate message to that effect is addressed to Mr. Heinemann.

With every confidence that our efforts to collect everything known about the most famous horse ever bred will meet with indulgent and sympathetic assistance of all Englishmen who have facts to contribute,

We are, Sirs, faithfully yours,

April 19th, 1906. THE AUTHORS.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

A Hospital Incident.

THE evidence given at an inquest held on April 23rd by the city coroner on a 12 months old child illustrates one of the modes by which reports likely to injure hospitals are sometimes originated. The child was scalded on Good Friday and after treating him herself the mother took him to the Ancoats Hospital, having no money for private medical advice. She stripped the boy at a nurse's request and was then told she would have to obtain a "recommend." This she did and took the child the next day again to the hospital. According to the woman's statement, she was then told that she wanted horsewhipping and that the case was out of the district, and added that she subsequently obtained some money but that the child died before the medical man had seen him. This does not read very pleasantly. However, the secretary of the hospital denied the statement as to horsewhipping and said the essence of the case was that the mother wanted the child treated at home but that it was out of the house-patient district. When he saw her he told her to wait while he consulted the medical officer as to the advisability of taking the child as an in-patient but she had gone when he returned and he could not communicate with her. The coroner said that so far as the woman was concerned the whole affair was an unfortunate misunderstanding. It does not appear that the child was seen at the hospital by anyone but a nurse, who, it may be, was not effusively sympathetic, if we may judge by the impression apparently left on the woman's mind that she had been told she deserved horsewhipping. Such women are often trying and nurses are often tired; but it seems a pity that no one told this woman at first where she ought to take the child. The jury agreed that no reflection could be cast on the hospital officials and that the death was "accidental." No hospital, not even one doing such good work in a poor district as is done by the Ancoats Hospital, can always avoid "incidents."

Dissatisfied Antivaccinationists.

The Northern Counties Union of Antivaccination Societies had its annual conference in Manchester on April 21st. It resolved that it felt profound surprise and disappointment at the unsympathetic attitude of the Government towards even the smallest demands of conscientious objectors to vaccination, as well as at various other enormities,—as, e.g., "the callous indifference of the Home Secretary, the Lord Chancellor, and the Cabinet generally to the flagrant manner in which many magistrates persistently bully and catechise applicants for exemption certificates and refuse to give them their statutory rights." The meeting further urged efforts to be made to relieve "public servants and parents who desire to keep themselves and their children healthy from the intolerable persecution they now suffer at the hands of medical men and other officials, whose legal but monstrous business it is to corrupt the blood of the people and to make health a crime." To the sober-minded medical man who has hitherto been unconscious that it is his "legal but monstrous business to corrupt the blood of the people," towards whom, indeed, he has a kindly, benevolent feeling, the words quoted seem to belong to the category now termed "wild and whirling." These people, obsessed with one idea and impervious to any other, cannot be reasoned with. Most of them are sincere, in the sense of being terribly in earnest, so much so indeed that they shut their eyes to, or pervert, facts without any hesitation. The misfortune is that they did not live, say, a century ago, when they would have had object lessons as to the ravages of small-pox that would have saved them from the mischievous folly which they are doing their best to perpetrate. It rarely happens that cranks are eccentric, shall we say, on one point only, and it would be interesting to learn in what other directions the antivaccinationists run counter to the knowledge and common-sense of mankind.

Medical Man charged with Murder.

It is happily a rare thing for a qualified medical man to be charged with a criminal offence. On April 23rd, however, Mr. C. J. Holtom, M.R.C.S. Eng., L.S.A., was committed for trial on the charge of murdering a young woman who died, it was said, after the performance of what the newspapers euphemistically call an "illegal operation." No comment can be made on the case while *sub judice*.

April 24th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Dangers in Connexion with Pit Heaps.

IN mining districts there is scarcely a village without its "pit heap," often an ugly eye-sore by day and less often the only luminous object in the black darkness of night. Only those heaps which are known to be "alive" are looked on as dangerous, familiarity having bred so great a contempt for all others that almost without exception they have become the playgrounds for the village children. But every now and then some untoward occurrence serves as a reminder that fire may linger long and be none the less likely to burn. Quite recently the whole north country was startled by the death of two old people at Pelton who were poisoned by the fumes from such a smouldering heap, while several residents in the same village were driven from their homes by the stifling dangerous fumes. Scarcely has this excitement abated before we are again reminded of the danger at our very doors by the death of a little child who was fatally burned through falling into a hole on the side of a burning heap. This accident happened at New Lambton in the county of Durham. The heap in question was supposed by the residents to be burnt out and perfectly safe, for they allowed their children to use it as a playground. When the accident happened the deceased, aged one year and nine months, and two other children, aged three and five years respectively, were playing together when the ground suddenly gave way, leaving a burning hole four feet in diameter, into which the youngest child fell. The child was so much burnt that death occurred two and a half hours after the accident. At the inquest the colliery manager stated that the heap was a deposit of shale about 300 yards square and that there was a very slow combustion going on but he had not known of any gases coming from it during his ten years' experience. There was a pleasant view from the heap and the men were in the habit of going there with their children, though they did so at their own risk. Some 12 years ago a thousand tons of sand were put on the heap with a view of rendering the combustion as low as possible, but this only hindered combustion and did not entirely extinguish it. The colliery company has decided to put a wire fence round the heap and to affix notice boards warning the public of the danger.

The Local Lessons of the French Mining Disaster.

The Northumberland miners have decided that the moral for them is the necessity for prevention. They have accordingly passed resolutions suggesting that "salvage corps and approved apparatus be established at every pit and that the Government be called upon to enforce the formation and efficiency of such corps." It is further suggested that in the workings of every pit there should be one or more refuges adequately provided with a store of tinned meats and other provisions, &c.

Heath Bequest for Newcastle Nurses.

The trustees of the Heath Bequest (under the will of the late George Yeoman Heath) with the approval of the Charity Commissioners have elaborated a scheme which will materially benefit the nurses of Newcastle. The income from this bequest amounts to almost £220 annually, which the trustees have decided to divide in the following manner. About one-half is to go to the training institutions and the other half to the nurses' homes. Prizes amounting to £52 10s., together with a silver medal, will be awarded annually to the nurses of the Royal Victoria Infirmary. Of this sum £15 in five prizes go to the probationers; £20 in four prizes and a silver medal to the nurses up for their final examination; and £17 10s. in three prizes to the sisters. The conditions of the sisters' examination are that one-fifth of the marks shall be allotted for the general administration and discipline of the wards, one-fifth for the capability and application shown by them in the instruction and training of the probationers under their special charge and the balance of the total marks will be allotted for a competitive examination in medical and surgical nursing, including invalid cookery. Prizes amounting to £10 will be awarded for a competitive examination among the nurses of each of the following institutions: the Children's Hospital, the Lying-in Hospital, the Infectious Diseases Hospital, and the Union Hospital. The trustees also propose to pay one-fourth of the premiums paid by nurses in the different nurses' homes in Newcastle and Gateshead to the Royal National Pension Fund for Nurses not exceeding a sum of £2 to any one nurse in one year.

The Fees of Colliery Surgeons in Northumberland.

In my note in THE LANCET of March 17th, p. 794, it was pointed out that the decision of the Northumberland Miners' Association not to abolish the doctors' fees committee required confirmation by the various lodges throughout the county. Contrary, perhaps, to expectation the lodges have now decided by a large majority that the doctors' fees committee is to be abolished, so that the whole question is now taken out of the hands of the Central Union and becomes a purely local one, the men now having the power to deal directly with their medical men. This means that the dispute is practically at an end, though dissatisfaction still lingers in one or two districts, notably Ashington and Walbottle. But those of the miners who try to introduce medical men at the lower rates of remuneration have not an easy task. The medical men who have accepted the positions have often been found wanting and one has recently appeared in the police court charged with wife desertion! They also complain that there is a tendency on the part of druggists to boycott the medical men who are willing to take the reduced fee. To get over their many difficulties one section of the miners advocates the abolition of the present system and suggests the formation of a "sinking fund"—that is to say, that every man should pay into one common fund, and when the aid of a medical practitioner is required that he should be called in and make his ordinary charge, payment to be made out of the common fund. In connexion with the whole question it is interesting to note that from returns sent in from 53 collieries in Northumberland I learn that the rate of remuneration is as follows: at 41 collieries the payment is 9*d.* per fortnight, at seven 8*d.*, at three 6*d.*, at one 1*s.*, and at another 1*s.* 6*d.*

April 2[illegible]th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Conveyance of Milk by Railways.

AT a meeting of the West of England and South Wales branch of the Incorporated Society of Medical Officers of Health recently held at Cardiff Dr. E. Walford, the medical officer of health of Cardiff, brought forward a question of some importance in connexion with the conveyance of milk by railway companies. It appears that a milk dealer was recently fined by the Cardiff stipendiary magistrate in the sum of £20 as the result of the examination of a sample of milk taken at 3 A.M. from one of the dealer's churns at the railway station, the examination revealing only 2·52 per cent. of milk fat. The defence raised was that the churn when it left the farm on the previous evening contained 18 gallons and that one gallon consisting chiefly of cream which had risen to the top had been abstracted. No evidence in support of this ingenious defence was, however, forthcoming. Dr Walford dwelt upon the necessity for measures being taken to prevent the tampering with the contents of milk churns during transit. In order to ascertain the views of those engaged in the milk trade he had addressed to some of the largest dairy farmers in Somersetshire and Gloucestershire the following questions:—1. Do you consider that the present methods which are generally adopted by the railway companies for conveying milk in railway vans afford adequate protection from fraud of the milk? 2 Can you suggest any improvement in the methods adopted? 3. Do you approve of sealed or locked churns? 4. If not, what are your objections to such churns? 5. What form of churn do you consider most suitable? Two of the 12 farmers who replied to these inquiries were quite satisfied with the present methods. All the others complained that milk is frequently conveyed in guards' vans with all sorts of other goods such as fish and vegetables and sometimes even with dogs or calves. They were greatly in favour of special milk vans, properly ventilated and kept at a suitable temperature. They were nearly all in favour of locked churns. It is of interest to learn that nearly seven years ago the Railway Companies Association, in reply to an inquiry, informed the Board of Trade that "senders have for a long time been allowed to send milk in sealed cans, the companies accept the declaration of the senders as to the quantity conveyed, no extra charge being made, the only condition being that the tare weight of the cans shall be stamped upon the outside of the cans, so that in case of doubt the quantity of milk within the churn can be approximately ascertained by allowing 10¼ pounds for each gallon on milk declared." Dr. Walford emphasised the importance of keeping the milk under supervision from the time it leaves the cow until it reaches the milk depôt, fresh and clean unsterilised milk being in his opinion a more suitable food for infants than sterilised milk. Milk drawn from the udder with strict aseptic precautions, if not sterile, is at least, he maintained, comparatively free from bacteria, and if strained and cooled to 40° F. and kept at this temperature during transit the multiplication of bacteria is sufficiently arrested for all practical purposes. In the course of the discussion Dr. Francis T. Bond expressed the opinion that there would be little or no improvement in the methods of production and distribution of milk unless the milk consumers brought pressure to bear upon the purveyors who in their turn would have to compel the middleman and the dairy farmer to conform to the present-day ideals of cleanliness.

The Qualifications of Inspectors of Nuisances.

The Local Government Board has been recently making more detailed inquiries than was formerly the case into the qualifications for the duties of the office of newly appointed inspectors of nuisances. One of the latest instances is in connexion with the appointment of such an official for the rural district of Leominster in Herefordshire. The inspector who had been in office about 20 years having resigned, the district council advertised for a successor and more than 100 persons responded, although the salary offered was only £70 per annum, with no allowance towards the expenses entailed in getting about the district. Among those who applied for the post were several men who held a certificate of competency from the Royal Sanitary Institute or who were otherwise specially qualified. The district council did not elect one of these and upon applying to the Local Government Board to sanction the appointment of another candidate it received a communication from the Board asking for the special reasons which led the council to make this particular selection as the person chosen appeared to have no previous experience of the duties of the office of inspector of nuisances. In the course of its reply to the Board the district council stated that its nominee proposed to enter for an examination for inspectors of nuisances during the next few months, whereupon the Board intimated that for the present its sanction to the appointment would be withheld but would be given in the event of a proper certificate of proficiency being obtained within a year. The Board is to be congratulated upon the firm stand it has taken which is so entirely in the interests of the public health.

The Aberystwyth Board of Guardians and its Medical Officer.

The Aberystwyth guardians were informed at their meeting on April 16th that the assistance rendered by the infirmary house surgeon would be withdrawn at the end of April. Mr. W. Thomas, the ex-mayor, said that he was satisfied that they had done the right thing and he now proposed that a copy of the letter should be sent to the Local Government Board with an intimation that the guardians had no medical officer in view and threw the responsibility for the entire care of the sick inmates on to the shoulders of the Local Government Board. This was seconded by Mr. E. Morris and on being put to the vote was carried.

The Bridgwater Rural District Council and its Medical Officer of Health.

The Bridgwater rural district council recently decided to reduce the salary of its medical officer of health from £70 to £60 per annum. The Local Government Board, however, does not approve of this proceeding, and at a meeting of the rural council held on April 11th a letter was read from the Board advising the council to reconsider its decision and contending that the reasons for the proposed reduction were insufficient. It was proposed that the original salary should be paid and this was seconded, but eventually an amendment was carried by 8 votes to 5 to the effect that the Local Government Board should be informed that the council, after having fully considered the matter, is of opinion that it is fully justified in making the reduction.

April 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Motor Ambulance for Glasgow.

BY next month the St. Andrew's Ambulance Association will have on the road a new and specially equipped motor ambulance. This vehicle, it is expected, will extend the sphere of the society's usefulness in the Glasgow district and its work will be of interest far beyond the city, being one of the first of its kind in use in the United Kingdom. The motor ambulance when complete will have accommodation for two accident cases in ordinary circumstances but it is to be so constructed that it will accommodate more than double that number in an emergency. It will be lighted by electric light, and a red cross lamp will light its path at night and a glass transparency indicate during the day the mission which it fulfils. With the motor ambulance it will be possible to attend accidents on the fringe of the wide Glasgow district and to insure a much more speedy journey for the unfortunate injured to the various infirmaries.

The "Alice Mary Corbett" Memorial Nurses' Home.

This home, given by Mrs. Polson to the Glasgow Samaritan Hospital for Women in memory of her daughter, the late Mrs. Cameron Corbett, was opened recently and formally handed over to the governors of the hospital. This new addition to the hospital consists of three storeys and accommodation is provided for 28 nurses, each nurse having a separate apartment, while a suite of rooms is reserved for the matron. A large drawing-room for the nurses is situated on the ground floor. The building, which with the site has cost £10,000, has also been furnished at the donor's expense.

Relief of Incurables.

Under the management of the Glasgow and West of Scotland Association for the Relief of Incurables there are two homes—the Lanfine Home for patients suffering from pulmonary tuberculosis and not considered suitable cases for admission to a sanatorium, and the Broomhill Home, into whi patients suffering from other ailments are admitted. T medical officer's report for the past year shows that in t Broomhill Home at the end of December, 1904, there were 1 patients under treatment, as compared with 117 in 190 while in the Lanfine Home there were ten patients, against 13 at the end of 1905. One point which is ve satisfactory is that in the Lanfine Home, although intende for those cases not considered suitable for sanatoriums owi to the advanced stage of the disease, one patient was di missed as cured during the year, while five left the hon considerably benefited. The advantage of such a home f advanced cases of pulmonary tuberculosis is very evident bot to the patients themselves and also to those who as inmat of dwellings from which the patients have been remove are extremely liable to be infected with the disease. It to be noted with regret that for the year there is a deb balance of £1465 and on this account the directors will unable for the present to carry out any further extensio and thus during the next year there can be no mo admissions to the Broomhill Home except owing to the deat or removal of inmates.

Small-pox among Alien Emigrants.

In a report to the Glasgow town council Dr. A. K. Chalmer medical officer of health of Glasgow, draws attention some grave defects in the housing and inspection of alie emigrants detained in Glasgow for a longer or shorter perio while waiting for the steamer to convey them to Americ A case in point is that of a Russian Jew who was admitte to hospital on March 26th suffering from small-pox. H arrived from Russia *viâ* Rotterdam and Grangemout on March 22nd and with four others was accommodate in one of the hotels of the city. On the evening o admission he visited the shop of a fellow countryman who observing an eruption on his face, took him to another hote which is also used by emigrants and at once communicate with the medical officer of the shipping company concerned In this latter hotel the patient was detained in a room b himself but in the previous hotel he occupied two room in succession and had opportunities for mixing wit between 400 and 500 people who were accommodated i the hotel. The Aliens Act, 1905, holds the shippin companies responsible for the completion of transit o such persons as they have introduced into this country but while in Glasgow, as this case illustrates, infectio from a small-pox patient may reach a considerabl section of the resident population before its presence recognised. It would therefore seem desirable that so lon as this traffic continues these emigrants should be housed b themselves and regularly inspected so that the public ma have a reasonable degree of protection against importe disease. It is worthy of note also that there is no daily medical inspection of emigrants, although the interpreters employed are expected to intimate at once any case of sickness coming under their notice.

Commemoration Day at the University of Glasgow.

On April 18th the University of Glasgow was *en fête* to celebrate Commemoration Day. An elaborate programme was carried through, the most interesting item being an oration by Professor Henry Jones on Francis Hutcheson, who was professor of moral philosophy in the University from 1730 to 1746. At the conclusion of the address honorary degrees were conferred on several distinguished individuals.

April 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal University of Ireland.

A MEETING of Convocation of the Royal University of Ireland was held in the University Buildings on April 20th, Mr. Edward Cuming, M.A., barrister-at-law, presiding. After other business had been transacted Dr. J. C. McWalter, M.A., proposed a motion that lady graduates should be entitled ecome members of Convocation. The Rev. Mr. Leslie that he quite agreed with the motion and would support rovided that the Senate endeavoured to obtain powers to ntain order amongst the male graduates. He moved the owing amendment :—

> *ovided that the Senate* seeks such alteration in the Charter as will it sufficient power to maintain order and discipline in this versity.

Rev. Mr. Pillor seconded the amendment. The amendnt was not, however, pressed and the original motion carried. With reference to the disorders which had en place the *chairman* said that he regretted and connned as much as anyone the proceedings which took place the *conferring of degrees* in October last. He considered t they were offensive and objectionable but as a member the Senate for many years he was strongly of opinion that vas not for the benefit of harmony in the University or of iversity education that they should *hold a discussion on* s matter six months after it took place. He thought that very exaggerated importance had been given to the tter and to those who took part in it. Subsequently, . John Campbell of Belfast was elected a member of the nate in place of his honour Judge Shaw, K.C., resigned. e following was the result of the voting: Dr. J. Campbell, 8 votes; Dr. E. Magennis, 106; and Mr. Perry, C.E., 61. ere was one spoiled vote. Dr. Campbell is the President the Royal University Graduates' Association. His election ll strengthen the medical side in the Senate.

Tughan v. Darnell.

It was announced last week that the notice of appeal gainst the verdict in this celebrated case has been withawn, which leaves the result as a verdict for the plaintiff. he case, it will be recollected, was brought against a edical man for alleged negligence. At the first trial the ry *disagreed*, at the *second* they found for the defendant, d at the third for the plaintiff. Two special points of reat interest *to* the medical profession came up in this ial. The judge (the Lord Chief Baron Palles) decided at the ordinary custom or practice followed by the edical profession could not be regarded as evidence or of alue unless tested by the jury *in its bearing* upon the articular case at issue. The other question was the efinition of negligence. Previously judges had laid down he rule that negligence meant want of skill, but that in edical matters, owing to the nature of the *science*, the ame exactness could not be expected which would be emanded in the case of an engineer who is controlled by istinct limitations recognised by everyone. The Chief Baron, in the Darnell case, quoted a definition (he did not give the name of its author) of negligence which will, if it s now to be the accepted one, make medical practice very difficult. Negligence on the part of the medical man, he said, was want of consummate skill, care, and foresight. One can understand a medical man being expected to have care and skill. If this care and skill are to be "consummate" it is bad enough, but if in addition he is to show consummate foresight I am afraid legal actions against members of the medical profession will increase tenfold. Imagine lawyers being compelled to live up to such a test.

Mater Infirmorum Hospital, Belfast.

From the twenty-second annual report of this hospital it appears that during the past year there were 1525 interne patients, 3762 accidents, and 22,597 out-patient cases. 389 surgical operations were performed. The total number of patients who received treatment was 27,884, being an increase of 1517 as compared with the year 1904. The *most* notable increase is in the number of accident cases. The expenditure was for the past year £5152. The increase of expenditure over income during the past two years leaves a balance *due to the bank* of £257 19*s*. 9*d*. Additional funds are urgently required.

April 24th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Consolidation after Dental Grafts.

THE mechanism of consolidation after dental grafts has been studied experimentally by M. Mendel who recently read a paper on the subject before the Anatomical Society. Microscopic sections show that if an extracted tooth be immediately replaced the alveolo dental membrane takes on all the work of consolidation and it is impossible to distinguish between the sections of a re-implanted tooth and of a normal tooth. If, however, the grafted tooth be dry—i.e., not freshly extracted—an ossifying process is brought about, callus develops, and the alveolo-dental membrane plays no part.

Drug Eruptions.

At a meeting of the Hospitals Medical Society *held* on March 23rd M. Gaucher, M. Boisseau, and M. Desmoulières communicated a paper dealing with a case of drug eruption alternating with bronchitis in a patient suffering from cystinuria. He was 40 years of age and there was nothing in his history to show that he would be specially susceptible to drugs. Up to the age of 26 years he had taken no medicine except an *occasional* purgative. About that date, however, he was attacked with abdominal pain and he took three drops of cherry laurel water, equal to seven-tenths of a milligramme of hydrocyanic acid. Twelve hours later he was attacked with a vesicular eruption which spread rapidly all over his trunk and the upper part of the thighs. This rash lasted for some 15 days. On Feb. 8th of this year he suffered from bronchitis and he took one dose of a mixture containing sulphate of sparteine, syrup of narceine, belladonna, and cherry laurel water. During the same night he was attacked with an urticarial eruption which was extremely irritable. On the following day desquamation commenced, which rapidly became generalised and which lasted for four days. While the rash and desquamation lasted he had no cough or any sign of bronchitis. On Feb. 14th the cough returned, so he took another dose of the same mixture with the exception that the cherry laurel water was omitted and chloral was substituted. A few hours later an eruption similar to the last appeared and disappeared at the end of five days. The cough was again arrested and did not return until 10 days later. On March 8th he took a dose of a mixture containing belladonna, narceine, thebaine, and codeine. An eruption followed similiar to the two former and the cough ceased. On March 12th the patient entered the hospital. He had no signs of disease except a generalised desquamation. Two days after the desquamation had *ceased and* the cough reappeared but was not so violent as formerly. Apparently the eruptions were *produced by the cherry* laurel water and the belladonna, although it is possible that the opium alkaloids *were in fault*. The *urinary* sediment examined under the microscope showed numerous crystals *of cystine and analysis* showed a marked diminution in the oxidation products of sulphur and nitrogen, but there were present various allied *sulphonic derivatives* such as characterise abnormal intestinal fermentations.

Cerebral Tumour; Removal; Recovery.

At a meeting of the Surgical Society held on April 4th M. Legueu showed a patient on whom he had operated for cerebral tumour. The growth was a glio-sarcoma occupying the lower third of the ascending frontal and parietal convolutions and bridging over the fissure of Rolando. The patient on admission to the hospital suffered from attacks of Jacksonian epilepsy and left hemiplegia. As he had had syphilis and had also sustained an injury to his skull an exact diagnosis before operation was impossible. The growth was easily removed and since the operation the epileptic attacks have ceased and the hemiplegia has completely disappeared. The patient is now quite well, he can walk, and can do a good day's work. M. Legueu said that he would not commit himself to say whether the cranial injury was the consequence of a vertiginous attack, which was the first symptom of an already existing tumour, or whether the cranial injury had in some way or other brought about the growth.

April 23rd

MR. WILLIAM HENRY WATERFIELD, L.R.C.P., L.R.C.S. Irel., has been re-elected vice chairman of the Stonehouse (Plymouth) board of guardians.

PRESENTATION TO A MEDICAL PRACTITIONER.—At the Public Hall, Liskeard, Cornwall, on April 20th, Mr. George Stephen Meadows, M.B., C.M. Edin., was presented with a silver salver and a pair of silver candlesticks by the members of Bodmin, Liskeard, Looe, Mutley, Saltash, and Torpoint Choral Societies as a mark of their respect and esteem and a slight acknowledgment of the gratuitous musical services which Dr. Meadows had rendered to the societies.

rural district of Leominster in Herefordshire. The inspector who had been in office about 20 years having resigned, the district council advertised for a successor and more than 100 persons responded, although the salary offered was only £70 per annum, with no allowance towards the expenses entailed in getting about the district. Among those who applied for the post were several men who held a certificate of competency from the Royal Sanitary Institute or who were otherwise specially qualified. The district council did not elect one of these and upon applying to the Local Government Board to sanction the appointment of another candidate it received a communication from the Board asking for the special reasons which led the council to make this particular selection as the person chosen appeared to have no previous experience of the duties of the office of inspector of nuisances. In the course of its reply to the Board the district council stated that its nominee proposed to enter for an examination for inspectors of nuisances during the next few months, whereupon the Board intimated that for the present its sanction to the appointment would be withheld but would be given in the event of a proper certificate of proficiency being obtained within a year. The Board is to be congratulated upon the firm stand it has taken which is so entirely in the interests of the public health.

The Aberystwyth Board of Guardians and its Medical Officer.

The Aberystwyth guardians were informed at their meeting on April 16th that the assistance rendered by the infirmary house surgeon would be withdrawn at the end of April. Mr. W. Thomas, the ex-mayor, said that he was satisfied that they had done the right thing and he now proposed that a copy of the letter should be sent to the Local Government Board with an intimation that the guardians had no medical officer in view and threw the responsibility for the entire care of the sick inmates on to the shoulders of the Local Government Board. This was seconded by Mr. E. Morris and on being put to the vote was carried.

The Bridgwater Rural District Council and its Medical Officer of Health.

The Bridgwater rural district council recently decided to reduce the salary of its medical officer of health from £70 to £60 per annum. The Local Government Board, however, does not approve of this proceeding, and at a meeting of the rural council held on April 11th a letter was read from the Board advising the council to reconsider its decision and contending that the reasons for the proposed reduction were insufficient. It was proposed that the original salary should be paid and this was seconded, but eventually an amendment was carried by 8 votes to 5 to the effect that the Local Government Board should be informed that the council, after having fully considered the matter, is of opinion that it is fully justified in making the reduction.

April 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Motor Ambulance for Glasgow.

BY next month the St. Andrew's Ambulance Association will have on the road a new and specially equipped motor ambulance. This vehicle, it is expected, will extend the sphere of the society's usefulness in the Glasgow district and its work will be of interest far beyond the city, being one of the first of its kind in use in the United Kingdom. The motor ambulance when complete will have accommodation for two accident cases in ordinary circumstances but it is to be so constructed that it will accommodate more than double that number in an emergency. It will be lighted by electric light, and a red cross lamp will light its path at night and a glass transparency indicate during the day the mission which it fulfils. With the motor ambulance it will be possible to attend accidents on the fringe of the wide Glasgow district and to insure a much more speedy journey for the unfortunate injured to the various infirmaries.

The "Alice Mary Corbett" Memorial Nurses' Home.

This home, given by Mrs. Polson to the Glasgow Samaritan Hospital for Women in memory of her daughter, the late Mrs. Cameron Corbett, was opened recently and formally handed over to the governors of the hospital. This new addition to the hospital consists of three storeys and accommodation is provided for 28 nurses, each nurse having a separate apartment, while a suite of rooms is reserved for the matron. A large drawing-room for the nurses is situated on the ground floor. The building, which with the site has cost £10,000, has also been furnished at the donor's expense.

Relief of Incurables.

Under the management of the Glasgow and West of Scotland Association for the Relief of Incurables there are two homes—the Lanfine Home for patients suffering from pulmonary tuberculosis and not considered suitable cases for admission to a sanatorium, and the Broomhill Home, into which patients suffering from other ailments are admitted. The medical officer's report for the past year shows that in the Broomhill Home at the end of December, 1904, there were 108 patients under treatment, as compared with 117 in 1905; while in the Lanfine Home there were ten patients, as against 13 at the end of 1905. One point which is very satisfactory is that in the Lanfine Home, although intended for those cases not considered suitable for sanatoriums owing to the advanced stage of the disease, one patient was dismissed as cured during the year, while five left the home considerably benefited. The advantage of such a home for advanced cases of pulmonary tuberculosis is very evident both to the patients themselves and also to those who as inmates of dwellings from which the patients have been removed are extremely liable to be infected with the disease. It is to be noted with regret that for the year there is a debit balance of £1465 and on this account the directors will be unable for the present to carry out any further extensions and thus during the next year there can be no more admissions to the Broomhill Home except owing to the death or removal of inmates.

Small-pox among Alien Emigrants.

In a report to the Glasgow town council Dr. A. K. Chalmers, medical officer of health of Glasgow, draws attention to some grave defects in the housing and inspection of alien emigrants detained in Glasgow for a longer or shorter period while waiting for the steamer to convey them to America. A case in point is that of a Russian Jew who was admitted to hospital on March 26th suffering from small-pox. He arrived from Russia *viâ* Rotterdam and Grangemouth on March 22nd and with four others was accommodated in one of the hotels of the city. On the evening of admission he visited the shop of a fellow countryman who, observing an eruption on his face, took him to another hotel which is also used by emigrants and at once communicated with the medical officer of the shipping company concerned. In this latter hotel the patient was detained in a room by himself but in the previous hotel he occupied two rooms in succession and had opportunities for mixing with between 400 and 500 people who were accommodated in the hotel. The Aliens Act, 1905, holds the shipping companies responsible for the completion of transit of such persons as they have introduced into this country, but while in Glasgow, as this case illustrates, infection from a small-pox patient may reach a considerable section of the resident population before its presence is recognised. It would therefore seem desirable that so long as this traffic continues these emigrants should be housed by themselves and regularly inspected so that the public may have a reasonable degree of protection against imported disease. It is worthy of note also that there is no daily medical inspection of emigrants, although the interpreters employed are expected to intimate at once any case of sickness coming under their notice.

Commemoration Day at the University of Glasgow.

On April 18th the University of Glasgow was *en fête* to celebrate Commemoration Day. An elaborate programme was carried through, the most interesting item being an oration by Professor Henry Jones on Francis Hutcheson, who was professor of moral philosophy in the University from 1730 to 1746. At the conclusion of the address honorary degrees were conferred on several distinguished individuals.

April 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal University of Ireland.

A MEETING of Convocation of the Royal University of Ireland was held in the University Buildings on April 20th, Mr. Edward Cuming, M.A., barrister-at-law, presiding. After other business had been transacted Dr. J. C. McWalter, M.A., proposed a motion that lady graduates should be entitled o become members of Convocation. The Rev. Mr. Leslie aid that he quite agreed with the motion and would support t provided that the Senate endeavoured to obtain powers to naintain order amongst the male graduates. He moved the ollowing amendment:—

> Provided that the Senate seeks such alteration in the Charter as will ive it sufficient power to maintain order and discipline in this University.

The Rev. Mr. Pillor seconded the amendment. The amendment was not, however, pressed and the original motion was carried. With reference to the disorders which had taken place the chairman said that he regretted and condemned as much as anyone the proceedings which took place at the conferring of degrees in October last. He considered that they were offensive and objectionable but as a member of the Senate for many years he was strongly of opinion that it was not for the benefit of harmony in the University or of university education that they should hold a discussion on this matter six months after it took place. He thought that a very exaggerated importance had been given to the matter and to those who took part in it. Subsequently, Dr. John Campbell of Belfast was elected a member of the Senate in place of his honour Judge Shaw, K.C., resigned. The following was the result of the voting: Dr. J. Campbell, 298 votes; Dr. E. Magennis, 106; and Mr. Perry, C.E., 61. There was one spoiled vote. Dr. Campbell is the President of the Royal University Graduates' Association. His election will strengthen the medical side in the Senate.

Tughan v. Darnell.

It was announced last week that the notice of appeal against the verdict in this celebrated case has been withdrawn, which leaves the result as a verdict for the plaintiff. The case, it will be recollected, was brought against a medical man for alleged negligence. At the first trial the jury disagreed, at the second they found for the defendant, and at the third for the plaintiff. Two special points of great interest to the medical profession came up in this trial. The judge (the Lord Chief Baron Palles) decided that the ordinary custom or practice followed by the medical profession could not be regarded as evidence or of value unless tested by the jury in its bearing upon the particular case at issue. The other question was the definition of negligence. Previously judges had laid down the rule that negligence meant want of skill, but that in medical matters, owing to the nature of the science, the same exactness could not be expected which would be demanded in the case of an engineer who is controlled by distinct limitations recognised by everyone. The Chief Baron, in the Darnell case, quoted a definition (he did not give the name of its author) of negligence which will, if it is now to be the accepted one, make medical practice very difficult. Negligence on the part of the medical man, he said, was want of consummate skill, care, and foresight. One can understand a medical man being expected to have care and skill. If this care and skill are to be "consummate" it is bad enough, but if in addition he is to show consummate foresight I am afraid legal actions against members of the medical profession will increase tenfold. Imagine lawyers being compelled to live up to such a test.

Mater Infirmorum Hospital, Belfast.

From the twenty-second annual report of this hospital it appears that during the past year there were 1525 interne patients, 3762 accidents, and 22,597 out-patient cases. 389 surgical operations were performed. The total number of patients who received treatment was 27,834, being an increase of 1517 as compared with the year 1904. The most notable increase is in the number of accident cases. The expenditure was for the past year £5152. The increase of expenditure over income during the past two years leaves a balance due to the bank of £257 19*s.* 9*d.* Additional funds are urgently required.

PARIS.

(From our own Correspondent.)

Consolidation after Dental Grafts.

The mechanism of consolidation after dental grafts has been studied experimentally by M. Mendel who recently read a paper on the subject before the Anatomical Society. Microscopic sections show that if an extracted tooth be immediately replaced the alveolo-dental membrane takes on all the work of consolidation and it is impossible to distinguish between the sections of a re-implanted tooth and of a normal tooth. If, however, the grafted tooth be dry—i.e., not freshly extracted—an ossifying process is brought about, callus develops, and the alveolo-dental membrane plays no part.

Drug Eruptions.

At a meeting of the Hospitals Medical Society held on March 23rd M. Gaucher, M. Boisseau, and M. Desmoulières communicated a paper dealing with a case of drug eruption alternating with bronchitis in a patient suffering from cystinuria. He was 40 years of age and there was nothing in his history to show that he would be specially susceptible to drugs. Up to the age of 26 years he had taken no medicine except an occasional purgative. About that date, however, he was attacked with abdominal pain and he took three drops of cherry laurel water, equal to seven-tenths of a milligramme of hydrocyanic acid. Twelve hours later he was attacked with a vesicular eruption which spread rapidly all over his trunk and the upper part of the thighs. This rash lasted for some 15 days. On Feb. 8th of this year he suffered from bronchitis and he took one dose of a mixture containing sulphate of sparteine, syrup of narceine, belladonna, and cherry laurel water. During the same night he was attacked with an urticarial eruption which was extremely irritable. On the following day desquamation commenced, which rapidly became generalised and which lasted for four days. While the rash and desquamation lasted he had no cough or any sign of bronchitis. On Feb. 14th the cough returned, so he took another dose of the same mixture with the exception that the cherry laurel water was omitted and chloral was substituted. A few hours later an eruption similar to the last appeared and disappeared at the end of five days. The cough was again arrested and did not return until 10 days later. On March 8th he took a dose of a mixture containing belladonna, narceine, thebaine, and codeine. An eruption followed simillar to the two former and the cough ceased. On March 12th the patient entered the hospital. He had no signs of disease except a generalised desquamation. Two days after the desquamation had ceased and the cough reappeared but was not so violent as formerly. Apparently the eruptions were produced by the cherry laurel water and the belladonna, although it is possible that the opium alkaloids were in fault. The urinary sediment examined under the microscope showed numerous crystals of cystine and analysis showed a marked diminution in the oxidation products of sulphur and nitrogen, but there were present various allied sulphonic derivatives such as characterise abnormal intestinal fermentations.

Cerebral Tumour; Removal; Recovery.

At a meeting of the Surgical Society held on April 4th M. Leguen showed a patient on whom he had operated for cerebral tumour. The growth was a glio-sarcoma occupying the lower third of the ascending frontal and parietal convolutions and bridging over the fissure of Rolando. The patient on admission to the hospital suffered from attacks of Jacksonian epilepsy and left hemiplegia. As he had had syphilis and had also sustained an injury to his skull an exact diagnosis before operation was impossible. The growth was easily removed and since the operation the epileptic attacks have ceased and the hemiplegia has completely disappeared. The patient is now quite well, he can walk, and can do a good day's work. M. Leguen said that he would not commit himself to say whether the cranial injury was the consequence of a vertiginous attack, which was the first symptom of an already existing tumour, or whether the cranial injury had in some way or other brought about the growth.

April 23rd.

Mr. William Henry Waterfield, L.R.C.P., L.R.C.S. Irel., has been re-elected vice chairman of the Stonehouse (Plymouth) board of guardians.

Presentation to a Medical Practitioner.—At the Public Hall, Liskeard, Cornwall, on April 20th, Mr. George Stephen Meadows, M.B., C.M. Edin., was presented with a silver salver and a pair of silver candlesticks by the members of Bodmin, Liskeard, Looe, Mutley, Saltash, and Torpoint Choral Societies as a mark of their respect and esteem and a slight acknowledgment of the gratuitous musical services which Dr. Meadows had rendered to the societies.

Obituary.

GEORGE BUCHANAN, M.D., LL.D. ST. AND., F.F.P.S. GLASG.

ONE of the links connecting the University of Glasgow with a past generation has been severed by the death at Stirling on April 19th of Dr. George Buchanan. Dr. Buchanan occupied the chair of clinical surgery in the University of Glasgow for many years, retiring some time ago on account of declining health. He was the son of Dr. Moses Buchanan who was lecturer on anatomy in the Portland-street School of Medicine, a school which has long since disappeared, and subsequently became professor of anatomy in Anderson's College. Dr. George Buchanan succeeded his father as Professor of Anatomy in Anderson's College and was appointed surgeon to the Glasgow Royal Infirmary. There he was a colleague of Lord Lister and did admirable work before the days of Listerism. It is worthy of note that when chloroform was introduced to the notice of the medical profession he was the first practitioner in Glasgow who volunteered to test the influence of the anæsthetic on himself. In 1874 he was appointed Professor of Clinical Surgery and at the same time became surgeon to the Western Infirmary, a post which he held with much acceptance and distinction until his retirement a few years ago.

Dr. Buchanan was a bold and skilful operator. It was he who first introduced the operation for excising half the tongue and he was also the first to excise the superior maxillary bone for cancer. As a teacher he was a great favourite among the students on account of the clearness and precision of his teaching and also because of his genial personality. By the death of Dr. Buchanan one of that small and fast dwindling group of medical men who served as surgeons in the Crimean war has been lost.

WILLIAM SCOTT CORE, M.D. R.U.I., L.R.C.S. EDIN.

Dr. W. S. Core, a well-known medical practitioner, died suddenly at his residence, Belfast, on April 21st, after an apoplectic seizure in his bath on that morning; he succumbed in three hours. The deceased, who was 59 years of age, was born in Caledon, being a son of Captain Core of the Tyrone Fusiliers. Studying at Queen's College, Belfast, he graduated M.D. in the old Queen's University and he also became L.R.C.S. Edin. Beginning practice 35 years ago he started in the same district of Belfast in which he resided until his death, and where, by his skill, attention, and kindness to patients, he surrounded himself with a large *clientèle*. For more than 30 years he was medical officer to the Northern Counties Railway (now owned by the Midland Railway Company). Dr. Core was an admirable musician and did much to improve the taste of the public with whom he was brought in contact in this art. He was also a well-known and highly respected member of the Masonic body. Dr. Core leaves a widow, one daughter, and three sons. He was buried in the city cemetery of Belfast on April 23rd, a very large concourse of friends and patients attending to show a last mark of regard.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Alexander Haslund, the well-known professor of dermatology in Copenhagen, aged 62 years.—Dr. V. Vleminckx, president of the Belgian Medical Academy.—Dr. Robert O. Doremus, formerly professor of chemistry and forensic medicine in the Bellevue Hospital Medical College, New York.

MEDICAL MAGISTRATE.—The name of Dr. Frank Russell of Heaton, Newcastle-upon-Tyne, has just been added to the commission of the peace for the city and county of Newcastle-upon-Tyne.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—A examinations held in April the following candidates pass in the subjects indicated:—

Surgery.—T. P. Braim, Leeds; L. C. W. Brigstocke (Section I St. George's Hospital; D. L. E. Gay (Section I.), Lausanne; J. H Harrison (Section II.), Sheffield; C. L Senn (Sections I and II Geneva; E. F. Thomas (Section I.), Middlesex Hospital; an P. C. W. Laws, Oxford and St. George's Hospital.

Medicine.—J. W. Blooker (Sections I. and II.), Amsterdam; H. A Fenton (Section I.), St. Mary's Hospital; D L. E. Gay (Section I Lausanne; O. P. N. Pearn (Section I), Westminster Hospital C. L. Senn (Sections I. and II.), Geneva; H. Smith (Section I. and II., Sheffield; E. F. Thomas (Section I.), Middlese Hospital; and A. P. Wright (Sections I. and II.), Glasgow an Liverpool.

Forensic Medicine.—J. W. Blooker, Amsterdam; H. A. Fenton, St Mary's Hospital; D. L. E. Gay, Lausanne; C. L. Senn, Genera H. Smith, Sheffield; and E. F. Thomas, Middlesex Hospital.

Midwifery.—R Beesloy, Manchester; D. L. E. Gay, Lausanne C. L. Senn, Geneva; and E. F. Thomas, Middlesex Hospital

The diploma of the Society was granted to the following candidate entitling them to practise medicine, surgery, and midwifery: T. P. Braim, J. H. Harrison, P. C. W. Laws, C. L. Senn, and A. P. Wright.

UNIVERSITY OF CAMBRIDGE.—Mr. Stanley Boy and Mr. L. A. Dunn have been appointed Examiners i Surgery and Dr. H. Morley Fletcher an Examiner i Medicine for the M.B degree.—The following candidate have passed the Sanitary Science Examination and ar entitled to the University Diploma in Public Health:—

K. V. Amin, H. B. Arbuckle, J. O. Bridge, T. Carnwith, J. T. Clarke C. V. Craster, C. Fraser, A. E. Hodgson, E. C. G. Maddock, J. A Mitchell, J. M. Morris, E. L Perry, W. Thorp, and W. J. Wilson

—Mr. W. Bateson, F.R.S., St. John's, has been appointe deputy for the Professor of Zoology and Comparativ Anatomy during the ensuing academic year.

UNIVERSITY OF DURHAM.—At the Second Examination for the degree of Bachelor in Medicine held recently the following candidates satisfied the examiners:—

Anatomy, Physiology, and Materia Medica.—Second-class honours Eldred Curwen Braithwaite, College of Medicine, Newcastle-upon Tyne. *Pass list:* Harriett Amelia Rachel Apps, London School of Medicine for Women; Charles Ernest Lewis Burman, and Leslie Wilson Evans, College of Medicine, Newcastle-upon-Tyne; Charles Westland Greene, Royal College of Surgeons, Ireland, and College of Medicine, Newcastle upon-Tyne; Arthur Charles Greene, College of Medicine, Newcastle upon-Tyne; Claude Percival Rivers Harvey, London Hospital, and College of Medicine, Newcastle-upon-Tyne; Edmund Hudson, M.R.C.S., L.R.C.P., St. Thomas's Hospital, and Annie Viccars Mack, Herbert Richard McAlconan, Stanley Larmond Randolph, Joseph Albert Sacco Rev. Robert Henry Smallwood, M.A., and Theodore William Stallybrass, College of Medicine, Newcastle upon-Tyne.

UNIVERSITY OF OXFORD.—J. Sholto C. Douglas, B.M., B.Ch., Christ Church, has been elected to a Radcliffe Travelling Fellowship.—The degree days appointed for the present term are as follows: Thursday, April 26th; Thursday, May 17th; Saturday, June 2nd; Thursday, June 14th; Thursday, June 21st; and Saturday, July 7th.—Examinations for scholarships in natural science will be held at Merton College, New College, and Corpus Christi College, commencing on April 24th, and at Brasenose College, commencing on June 26th.—There will be an election to a Fellowship at Merton College on Saturday, Oct. 6th, after an examination in the subjects recognised in the Honour School of Chemistry.—The examinations for the degrees of B.M., B Ch., will commence on Thursday, June 14th. Names must be sent in to the secretary to the Boards of Faculties not later than 10 30 A.M. on Tuesday, May 29th.—The examination for the degree of Master in Surgery will commence on Thursday, June 21st. Names must be sent in to the secretary to the Boards of Faculties not later than 10.30 A.M. on Friday, June 1st.

AN HISTORICAL MEDICAL EXHIBITION.—The exhibition of rare and curious objects relating to medicine, chemistry, pharmacy, and the allied sciences which is being organised by Mr. Henry S. Wellcome of the firm of Burroughs, Wellcome, and Co. will, as that gentleman announces in a preliminary programme, be opened shortly. It will be strictly professional and scientific in character and will not be open to the general public. The advance programme, which may be obtained on application to Mr. Wellcome, Snowhill Buildings, London, E.C., contains several curious and interesting illustrations taken from old manuscripts, while the cover of the programme is embellished on the front page with a coloured reproduction from an incised stone carving of I-em-hotep. In an introductory letter setting forth the objects of the exhibition, the organiser says, "It is my aim to bring together a collection of historical objects illustrating the development of the science and art of healing throughout the ages, ... in particular to trace the origin of the use of certain remedial agents. Why were certain substances used in the treatment of disease? Was their adoption the result of study and practical observation, or was it more usually the result of accident? Were the alleged virtues purely imaginary and due to some superstitious suggestion? .. ... I anticipate that the exhibition will reveal many facts, and will elucidate many obscure points in connexion with the origins of various medicines and in respect to the history of diseases. ... .. I shall greatly value any information sent me in regard to medical lore, early traditions, or references to ancient medical treatment in manuscripts, printed works, &c. Even though the items be small, they may form important links in the chain of historical evidence .. The greatest care will be taken of every object lent. All exhibits will be insured, and ...... packing and carriage both ways will be paid."

THE CHEMISTS' EXHIBITION.—The twelfth annual chemists' exhibition organised by the proprietors of the *British and Colonial Druggist* was opened at the Royal Horticultural Hall in Vincent square, Westminster, on Monday last and remained open until Friday, the 27th inst. The occasion is evidently one appreciated alike by wholesale and retail druggists and has primarily for its object the extension of business opportunities. The number of visitors was very satisfactory and many pharmacists from all parts of the country attended The exhibition is not without interest to medical men, inasmuch as the subjects of exhibition included medical and surgical appliances, drugs, special foods, and so forth. The exhibition affords also some interesting sidelights on the pushful ways adopted by the modern druggist to sell his wares We cannot help remarking that many of the exhibits had a strong flavour of quackery about them, as, for example, "The famous galvanic ring worn throughout the world for rheumatism, neuralgia, insomnia, and kindred ailments—the most profitable and quickest selling side line for chemists." Such an exhibit, we should have thought, would prove offensive to respectable pharmaceutical houses. Some of the stalls, though somewhat crowded together, were splendidly designed and made very attractive, a considerable sum of money evidently having been spent upon them. More in evidence, perhaps, than other wares were sponges, soaps, and perfumery, and a great number of proprietary articles, all of which now go to make up the counter sales of the modern druggist and pharmacist.

LONGEVITY.—Mr. F. Whitfield of Newport, Monmouthshire, celebrated the 101st anniversary of his birthday on April 6th.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 25TH

Compulsory Vaccination.

IN the House of Commons on Wednesday, April 25th, Mr. LUPTON called attention to the question of vaccination and moved "That in the opinion of this House vaccination ought no longer to be obligatory on those who regard it as useless or dangerous."

Mr J. M. ROBERTSON, who seconded the motion, declared that the law of exemption had been frustrated in all directions and in many cases grossly overridden. Applications for exemption had been often met by the most arrogant and insolent refusal because the magistrate avowed that he was not satisfied that the objector properly understood the subject. Some people had been inclined to think that the administration of the law would be considerably improved by sending a few magistrates to prison. He claimed that it was only by statistical proof that they could establish the value of vaccination and that he could judge of the results as well as a doctor or a magistrate. The Jenner Society existed in order to do justice to the reputation of Jenner, but the action of that society was a scientific imposture. The practice introduced by Jenner was no longer a part of the practice or theory of vaccination. Jenner's ground was abandoned nearly half a century ago. He was the means of establishing a penal law on a theory which had been repudiated and was no longer held by the representatives of vaccination. The vaccination of to-day was Pasteurism. That had nothing whatever to do with Jenner and the medical profession in this matter was seeking to gloss over and hide the fact that it had three times changed its ground and all the while been asking for compulsory powers from Parliament to apply a law which by its own confession had been wrong. They wanted to know when the profession began to be right. Instead of admitting that it had compulsion without just grounds it proceeded to bring forward new theories and they had now the theory that vaccination was useless without revaccination which was a negation of the ground on which vaccination stood for 60 years The history of the profession in this matter was a history of error tardily acknowledged and glossed over where possible. 60 years ago the profession gave to the world a declaration signed by 500 men to the effect that vaccination could not convey certain grave specific diseases. That was an error The medical profession had been always finding out that it was in error. They would never have the medical truth on this matter until vaccination was no longer endowed by the State. The resolution, he contended, was moderate and just in its terms. If it were not for the antivaccinators, in regard to whom the *British Medical Journal* adopted such a contemptuous and insolent tone, there would be little known about vaccination. He ventured to say that not one doctor in ten had read Crookshank on vaccination. The ignorant prejudice was not on the side of the anti-vaccinators but to a large extent on the side of the pro-vaccinators, who stood to a dogma which they had learned at College but who had not gone into the grounds on which that dogma could be justified. According to the statistics hundreds upon hundreds of children had been killed by vaccination and if this had been foreseen Parliament would not have agreed to compulsion. Vaccination was either a prophylactic or it was not. If it were a prophylactic a man might defend himself and his family against small-pox as far as he could If it were not a true prophylactic it was an iniquity. The medical profession could no longer deny that hundreds had been killed and many seriously injured by it. Coercion in the matter was monstrous and he asked the House to pass the resolution, trusting that it would elicit from the Government the legislation that was needed.

Mr PICKERSGILL having supported the motion.

The PRESIDENT OF THE LOCAL GOVERNMENT BOARD (Mr. BURNS) said he had not had a great deal of time to consider and decide the many points raised in the discussion. It had been pointed out that there was differential treatment of those who wished exemption and it was pointed out—he was afraid with some truth—that differentiation was made between the rich and the poor, between the educated and uneducated, and between those with a smattering of medical knowledge and those who were innocent of the terminology of the profession He might remind the House that the Act of 1898 was not absolutely compulsory as it allowed conscientious objectors to be exempted under certain conditions. The supreme difficulty was mainly administrative Injustice was due to lack of uniformity in administration and the capricious decisions of magistrates who sometimes behaved on the bench in this matter in a manner that was not creditable. He trusted that magistrates would cease to display differential treatment. With regard to the cost of vaccination, it had become more serious as the years went on. In 1899 the cost was £72,000, in 1900, £237,000, and now, £270,000 He believed the way in which the Act was administered provoked a spirit of resistance to vaccination where otherwise it would not exist He was considering the whole subject in the light of certain reforms which he thought were desirable and inevitable. The question of cost was sufficient to warrant departmental attention at once He was bending his mind to the amendment of the existing procedure in securing certificates of exemption. The Local Government Board considered that some reform in the direction of a statutory declaration being made by either parent at less cost than now would be necessary if the Act were to secure the harmonious coöperation of all sections of the community. He attached a great deal of importance to the temporary suspension of vaccination from early infancy to some sensible later period when the consequences to the individual would be greatly minimised. Further, the Local Government Board would institute an inquiry, for which a committee of the House would not be necessary, into the working of the Act. It thought that uniformity of practice was urgently desirable. He hoped, in view of his statement, that the motion would be withdrawn.

Mr. EUGENE WASON trusted that the Government would consider the claims of Scotland, which at present did not enjoy the liberty English people possessed of declaring a conscientious objection.

Sir W. J. COLLINS said that the Royal Commission of which he was a member was virtually unanimous on the point that the honest objector should not be subject to any penalty. If the Bill of 1898 had carried out the intentions of the Commission the House would not now be discussing this resolution. He could not endorse all that had been said of the profession to which he belonged but no professional man who had a reputation to lose would be prepared to maintain the position as regards the preventive power of vaccination or its innocence as regards injurious results which was originally proclaimed by Dr Jenner when he petitioned this House He was in favour of the abolition of compulsion He believed it would redound to the honour of the profession if they were free from association with the policeman and the bailiff and they would have greater confidence and respect from the public

The motion was by leave of the House withdrawn.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ABBOTT, HENRY KINGSMILL, M.D. Dub., D.P.H. Irel., has been appointed Medical Superintendent of the Hants County Asylum, Fareham.

BELL, T., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Uppingham District of the county of Rutland.

BERGIN, W. M., M.B., B.S. Lond., has been appointed Ophthalmic Assistant, Registrar, and Tutor at Guy's Hospital.

Bird, George William Harvey, M.B, B C Cantab, has been appointed Medical Officer of Health to the Bridgwater (Somerset) Port Sanitary Authority

Gardiner, Peter, M D, C M Glasg, D P H Lond, has been appointed Medical Officer for the Camborne District by the Redruth (Cornwall) Board of Guardians

Horgan, J, L R.C P & S Edin., L F P S Glasg, has been appointed Certifying Surgeon under the Factory and Workshop Act for the Kenmare District of the county of Kerry

Johnstone, John Lloyd, M R.C S, L R.C P, has been appointed Clinical Assistant to St. John s Hospital for Diseases of the Skin, Leicester-square.

Kerrawalla, M P, M D Brux, L R C P & S Edin, has been appointed Clinical Assistant to the Evelina Hospital for Children

Lane, J. S, *L R C P & S Irel*, has been appointed Certifying Surgeon under the Factory and Workshop Act for the Crettyard District of Queen's County

Longridge, C J Nepean, M D Vict. F R.C S Eng M R C P Lond, has been appointed Registrar and Pathologist to Queen Charlotte s Lying in Hospital, Marylebone-road, N W

May, Walter J, L R C P, M R C S, L D S, has been appointed Lecturer on Dental Mechanics at the Royal Dental Hospital of London Leicester-square.

Pearse, James, M D, C M Edin, has been appointed Medical Officer in charge of Troops at Trowbridge (Wilts)

Richards, P A Ellis F I C, F C S, has been appointed Lecturer on Dental Metallurgy at the Royal Dental Hospital of London, Leicester square.

Richmond, James Robert Marr L S A. has been appointed Medical Officer of Health of the West Penwith Rural District (Cornwall)

Rolston, John R., M R.C S Eng, has been appointed Honorary Ophthalmic Surgeon to the Royal British Female Orphan Asylum, Devonport.

Sheehan, M., M R.C S, L R.C P Lond has been appointed Certifying Surgeon under the Factory and Workshop Act for the Mallow District of the county of Cork

Thom, George, M R.C S, L S A., has been appointed Honorary Consulting Surgeon to the Royal Albert Hospital, Devonport.

Tizard Henry J, L R C P Lond., M R.C S, has been appointed Assistant Medical Officer to the Government Mental Hospitals of New Zealand

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Belgrave Hospital for Children, Clapham road, S W —Senior and Junior Resident Medical Officers for six months. Honorariums at rate of £20 and £10 a year respectively, with board and lodging

Birkenhead Borough Hospital.—Junior Resident House Surgeon. Salary £80, with fees

Bodmin, Cornwall County Asylum —Third Assistant Medical Officer, unmarried Salary £135 per annum, with board, apartments, washing &c.

Burley in Wharfedale, Scalebor Park (Private Asylum)—Assistant Medical Officer, unmarried Salary £150 per annum, with board, apartments attendance, &c.

Cambridge, University of Cambridge Pathological Laboratory —John Lucas Walker Studentship Annual value £200, tenable under certain conditions for three years

Canterbury, Kent and Canterbury Hospital.—House Physician, unmarried. Salary £90 a year, with board and lodging

Charing Cross Hospital.—Assistant Physician

City of London Hospital for Diseases of the Chest, Victoria Park, E —Resident Medical Officer Salary £100 per annum with board, &c Also Physician to Out patients Also Surgeon Dentist

Colchester Essex and Colchester General Hospital.—House Surgeon Salary £100 per annum, with board, washing, and residence

Coventry and Warwickshire Hospital.—Junior House Surgeon for six months, renewable *Salary £60 per annum, with rooms board*, washing, and attendance

Devonport Royal Albert Hospital.—*Resident Medical Officer*, unmarried Salary £100 per annum, with board and lodgings

Douglas, Isle of Man, Nobles Isle of Man Hospital and Dispensary —Resident House Surgeon, unmarried. Salary £90 a year, with board and washing

East Suffolk and Ipswich Hospital.—Third House Surgeon Salary £50

Evelina Hospital for Sick Children, Southwark, S E —Surgeon

Fareham, Hants County Asylum —Second Assistant Medical Officer, unmarried. Salary £175 per annum, with apartments, board, washing and attendance.

Gosforth, Newcastle-on Tyne City Asylum —Assistant Medical Officer, unmarried Salary £140 a year, *rising to* £160, with apartments, board and laundry

Hospital for Sick Children, *Great Ormond street* London W C —House Surgeon unmarried, for six months Salary £20, with board and residence

Hull Royal Infirmary —House Physician, unmarried Salary 80 guineas *per annum* with board and apartments.

Italian Hospital, Queen s-square, London, W C —Honorary Assistant Physician

Kensington General Hospital late "Queen s Jubilee," Earl s Court, London, S W —Assistant Dental Surgeon, Medical Registrar, Gynæcological Registrar (all honorary)

Leicester Infirmary —Assistant Surgeon.

Metropolitan Asylums Board Fever and Small pox *Hospitals* —Assistant Medical Officers Salary £160 per annum, rising to £240, with board lodging attendance, and washing

Metropolitan Asylums Board, Downs School Sutton Surrey (for Children with Ringworm —Assistant *Medical Officer* Salary £250 per annum and dinner

Miller *Hospital and* Royal Kent *Dispensary*, Greenwich roa S E —Junior Resident Medical Officer Salary £80 per annu with board, attendance, and washing

Mount Vernon Hospital for Consumption and Diseases of th Chest, Hampstead —Resident Medical Officer Honorarium £ per annum, with board, lodging &c.

Newport and Monmouthshire Hospital.—Junior Resident Medic *Officer* Salary £70 per annum, with board, residence, an washing

Oldham Infirmary —Junior *House Surgeon* Salary *£75 per annun* with board, residence and laundry.

Oxford, Littlemore Pauper Lunatic Asylum.—Second Assista Medical Officer, unmarried Salary £120, rising to £150, wit rooms and board

Plymouth, South Devon and East Cornwall Hospital.—Assistan House Surgeon for six months, renewable Salary at rate of £5 per annum, with board, residence, and washing

Royal Dental Hospital of London, Leicester square.—Assistan Dental Surgeon.

Sheffield Royal Hospital.—Honorary Assistant Surgeon Als Two Honorary Assistant Physicians.

Sheffield Union Hospital.—Resident Medical Officer Salary £10 per annum, with apartments, rations, and allowances. Als Resident Assistant *Medical Officer* Salary £80 per annum, wit apartments, rations, and allowances.

Society of Apothecaries of London —Examiner in Midwifery

Swansea General and Eye Hospital.—House Surgeon. Salary a rate of £50 per annum first six months, £75 per annum after, wit board, apartments, washing, and attendance.

Victoria Hospital for Children, Tite street, Chelsea, S W —Honorary Anæsthetist.

Warrington Infirmary and Dispensary —Junior House Surgeon unmarried Salary £100 per *annum*, with residence and board.

West Bromwich District Hospital.—Resident Assistant House Surgeon, unmarried. Salary £50 per annum, with board, residence and washing

West London Hospital, Hammersmith road, W —Assistant Anæsthetist. Also Second Assistant Anæsthetist. Also Casualty Surgeon

Western General *Dispensary*, Marylebone-road, N W —Honorary Surgeon.

Births, Marriages, and Deaths

BIRTHS

Curtis —On April 20th, at Lyndes Redhill, the wife of Frederick Curtis F R.C S Eng., *of a daughter*

Gabb —On April 17th at Cornwallis-gardens Hastings, the wife of Harry Secretan Gabb B A, M B, *B C*, *prematurely*, of a daughter (stillborn)

Gates.—On 21st April at Via Palestro A, *Florence*, Italy, the wife of Edward A. Gates, M D, M R C P, of a son

MARRIAGES.

Day—Williams —On the 21st inst, at St. George s Stonehouse, Plymouth, by the Rev J Gaud, assisted by the Rev Nicholson Watson vicar of St. George s, and the *Rev Walter Moyle* vicar of Ashcombe, Dawlish, William Frank Lydstone Day, M B B C *Cantab*, *youngest son of the late* Robert Newcombe *Day of Harlow* Essex and Dorothy Esther Katherine Williams younger daughter *of* F M. Williams medical officer of health for Plymouth.

Fox—Fox.—On April 19th at All Saints Church Holbeton, Edward Hamilton Bruce Fox, M R C S, L R C P, of *Woolston Lodge* Southampton, to Maude Geraldine *second daughter* of Charles Alfred Fox of Battisborough House, *Holbeton*

Macarthur—Sommerville.—On April 17th, at St Mary's Episcopal Church, Port-Glasgow William Forrest *Macarthur* M B, C.M, to Margaret, daughter of R G Sommerville, J P, Aldergrove, Port Glasgow

Pendred—Matthew —On April 23rd, at St. Barnabas, Addison road Kensington, by the *Rev J Grant* M A. assisted by the Rev T Guy Rogers B D, Vaughan Pendred M D, F R.C S Eng of Coventry, *eldest son of Vaughan Pendred*, M I M E, and Mrs. Pendred, of Crabill, Pendennis-road Streatham to Beatrice Elizabeth daughter of Dr and Mrs Mordaunt Matthew, of 22, Holland road Kensington, W

Pridmore—Paul.—On April 18th at Christ Church Westminster Eric Leonard Norman Pridmore M D, to Sophie Emily Marie Pauline Paul, daughter of the late Bernhard Ralph Paul of Shortlands, Kent.

Shuter—Saundby —On April 25th at Edgbaston *Parish Church* by the Rev Canon Foakes Jackson D D, Dean of Jesus College, Cambridge, *assisted* by the Rev A. *Roberton* Alfred Deve Shuter, M A Cantab., second son of William Shuter, 22, *Belsize*-grove *Hampstead to Marjorie* Spencer, daughter of Robert Saundby, M D, J P, Professor of Medicine in the *University of Birmingham*

DEATHS

Buchanan —At Balanton, Stirling on the 19th inst., *George* Buchanan, M A., *M D*, *LL D* aged 79, Emeritus Professor of Clinical Surgery Glasgow University

Hutton —*On the 24th inst*, at Lulworth House, Birkdale, Lancashire the residence of her *son* Dr D M Hutton *Eliza Peddie widow* of *David Hutton Esq.*, of Parkfield road Liverpool *and youngest* daughter of the Rev Peter Steele, M A, late *of Moray* House Training College Edinburgh in *her 69th year*

Scott —On the 24th inst., at Bury *Lodge* New Malden, Surrey, John Scott, F R.C S, late of *Harley street*, W, aged 90

Spackman —On April 21st, in *London*, Coniston Spackman, M R.C S, L.R.C P, aged 46

N B —A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

A WARNING.

To the Editors of THE LANCET.

SIRS,—I am reluctant to trespass upon your space but I shall be very glad if you will permit me to give my brother practitioners a word of warning through your columns; it may save them from being victimised as I have been. There is a certain practitioner at present doing locum work who has caused me annoyance and injury to an extent that is hardly credible. From what I hear he has treated other medical men in a similar manner and I wish to put my fellow practitioners on their guard against a man whom it is dangerous to employ. The person in question is an Eurasian (I make no complaint here against either Eurasians or Indians as a class) and can be identified by his extraordinary flow of eloquence upon the subjects of his own abilities and experiences. I confess I was not entirely free from suspicion as to his character when I engaged him at rather short notice to do a few weeks' locum work. Neither his appearance nor manner inspired confidence. I believe now that he wished to give me such a bad impression of him that I would be inclined to pay him a sum down to be released from the arrangement. I sincerely wish now that I had made the sacrifice. After I had left home he tried to give my family the impression that he was a dangerous man to cross. He boasted of having made himself so obnoxious to two former employers that they had severally offered him £100 to leave their neighbourhood. This I can readily believe. He also declared it was his habit to revenge himself upon any who had injured him in a manner quite Eastern in its completeness. On my return from the country I found a very unsatisfactory state of affairs. I discharged the man for insulting young girls, for neglect of duty, and for making libellous statements to the patients about myself. The man's conduct is hard to understand except on the hypothesis of mental trouble, for I had done nothing either by word or deed to arouse his hostility. He had no sooner left my house than he began a system of malicious persecution. He went round among my patients repeating his libellous statements and in some instances telling those who owed bills that they need not pay them, as the fees were not legally recoverable. This in one case necessitated my suing the debtor in the county court. As for the charges he made against me, they were so obviously untrue that I am glad to say very few of my patients gave them any credence. Not content with the revenge he had taken he called upon my dispenser and tried to get his assistance in opposing me and upon the dispenser's refusal he made use of threats. I discovered that during my absence he had called in a friend of his to pose as a consultant. He obtained a fee of £3 3s. for his friend and handed over the case to him entirely, of course to my detriment. No doubt the medical friend kindly acts as a reference in return for such favours. All I have stated is capable of legal proof. If any other medical practitioners who have had a similar experience to mine will kindly communicate with me through the medium of this paper it may be possible to bring the matter to the notice of the General Medical Council. It may be asked why I have not already taken legal proceedings instead of writing this letter. Well, an appeal to the law is expensive and tedious. I have neither the time nor the money to spare for a prosecution; nor have I written this letter for the gratification of revenge. I shall be content if through my action the medical profession is saved from further discredit and the public protected from insult and injury at the hands of a man of criminal tendencies. I inclose my card, and with apologies for the length of this letter,

I remain, Sirs, yours faithfully,

April 23rd, 1906. VICTIM.

⁂ The agent through whom the locum-tenent was obtained should be communicated with. If only a fraction of what our correspondent says can be proved to the satisfaction of a respectable agent Othello's occupation will be gone.—ED. L.

THE DURABILITY OF CARDIAC MUSCLE.

PROFESSOR LORTET, member of the French Academy, has published an interesting report upon the condition of the heart and viscera of King Rameses II. (the Greek Sesostris) after their embalmment for 3161 years. It seems that some months ago the governing body of the Musées Nationaux du Louvre in Paris acquired possession of four beautiful canopic vases covered with blue enamel and bearing the insignia of the ancient Egyptian monarch referred to. These were handed over to Professor Lortet for a chemical and microscopical examination of their contents, and Professor Hugounenq, Professor Renaut, and Professor Rigaud were associated with him in the work. Three of the vases were filled with linen bandages, impregnated with soda and glued together with aromatic resinous substances of a red colour. There were also present certain indeterminable granular substances, mixed with pulverised soda, which are conjectured to be all that is left of the stomach, the liver, and the intestines of the great king. The heart was found in the fourth vase, which is ornamented on the lid by a jackal. The appearance of the organ is that of an egg-shaped plate about eight centimetres long by four centimetres broad. Its tissue was found to be so solid and horny that in order to separate a portion from it recourse had to be had to the saw. A section was subsequently removed with a razor and submitted to the microscope, when the horny substance was seen to be composed of bundles of muscular fibre, arranged in the cross mesh peculiar to the formation of cardiac and glossal muscle. The tongue of King Rameses II. is, however, undoubtedly present in the royal mummy found in 1881 at Thebes and deposited in the Egyptian Museum at Cairo in 1886, so that there seems to remain no doubt that the organ observed by Professor Lortet is the heart. Rameses II. died 1258 B.C. The 3000 years that have since elapsed and the desiccating effect o soda and aromatic gums have been able to reduce the bulk of the king's heart but not to alter its anatomical formation, while the other viscera have been changed to unrecognisable dust.

MONSTERS.

To the Editors of THE LANCET.

SIRS,—I should be greatly obliged if, through the medium of your correspondence columns, any of your readers could give me information about the literature of fœtal malformation or "monsters."

I am, Sirs, yours faithfully,

April 17th, 1906. X.

AN UNFORTUNATE CIRCULAR.

A MEDICAL man, who makes no pretence of disinterestedness, writes as follows:—

> The following notice has been sent to every tenant of St. James' Court, Westminster, a block of residential flats in which I and many other medical men have patients residing. Two copies of this notice have been handed to me by patients on whom I am in actual attendance at the moment:—
>
> "The Resident Estate Manager begs to inform the Tenants of St. James' Court that Dr. W. Moyle O'Connor has taken up his residence in No. 43 and 44, Queen's House as Resident Physician to the Court, and that his services are available for the tenants at any time they may be required."

Dr. O'Connor will be well advised to check the resident estate manager's zeal in his behalf. Probably Dr. O'Connor knew nothing of that gentleman's ill-designed efforts, while the resident estate manager may be supposed to be ignorant of the fact that medical men, who are not allowed to advertise themselves, are also not allowed to benefit by the advertisements of others. We sympathise with the resentment of our correspondent.

IS BARLEY WATER A SUITABLE FOOD FOR INFANTS?

To the Editors of THE LANCET.

SIRS,—The letter of "Lacto" in THE LANCET of April 21st, p. 1150, shows very clearly the confusion which arises owing to the use of the terms caseinogen and casein for the chief proteid of milk and his implied protest is certainly wanted. Surely the time has come to abandon the use of the term "caseinogen"; philologically it is barbarous—casein is from the Latin *caseum*, gen is the Greek root γεν, and where the "o" comes from is a mystery. The root γεν means to beget and is quite rightly used in hydrogen, oxygen, &c., but in "caseinogen" it has apparently altered its meaning as this substance is not one which begets casein but which splits up into casein and other products of hydrolysis. Again, "caseinogen" forms salts with bases; are these to be called caseinogenates? and if so, how is the word to be pronounced? The so-called "casein" is really only one of a whole series of compounds produced by the hydrolysis of "caseinogen," and it is only the accidental property of the insolubility of its acid double salt with calcium phosphate that leads it to be produced. Surely, it is better to keep the name "casein" for the parent substance, as is done on the continent, in America, and by a large section of chemists in England. Let us wipe the monstrosity "caseinogen" from the language and avoid the confusion into which all sooner or later are led. I may instance this confusion by referring to a very recent book, Mann's "Chemistry of the Proteids"; in a footnote he states that he has adopted Halliburton's nomenclature; in the text he actually uses the words casein and caseinogen indiscriminately.

I am, Sirs, yours faithfully,

H. DROOP RICHMOND.

Woodfield-road, Ealing, W., April 21st, 1906.

THE EFFECT OF SUPERAERATED WATER UPON FISH.

UNDER normal conditions fish live in water which contains no more dissolved air than may be absorbed spontaneously at atmospheric pressure and the prevailing temperature. If, however, this amount is greatly exceeded—that is, if the water becomes superaerated, the fish exhibit remarkable symptoms often ending in death. A marked analogy exists between this affection and caisson disease in man. In the latter the body sustains an actual increase of pressure which is subsequently removed and the symptoms follow. This change of pressure has no counterpart in the case of the fish, except that the supersaturation of the water with the atmospheric gases is referable to an increase of pressure. At the station of the United States Bureau of Fisheries at Wood's Hole, Massachusetts, a quantity of sea water became supersaturated with air and the *Scientific American* of March 31st published some details of the effect produced. The absorption of air was due primarily to a leaky suction-pipe which allowed air to pass with the water into storage-tanks where it was subjected to a pressure of about eight pounds per square inch. From these storage tanks the water flowed to aquaria and being again at atmospheric pressure was in a condition of supersaturation with air. The fish showed a variety of symptoms. There was first a precipitation of very minute bubbles upon their bodies and fins, completely covering them. After a longer time small collections of gas formed in the skin, chiefly of the fins, and sometimes made the fish so buoyant that they could scarcely keep below the surface. Death resulted after a longer or shorter time from gas embolism or the presence of free gas within the blood-vessels. Often the vessels of the gill filaments were filled with gas and the ventral aorta and bulbus of the heart were distended with it and quite empty of blood. This gas contained about 97 per cent. of nitrogen.

HOW TO MAKE "HUMANISED" MILK.

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent "B. (Medicus)" in THE LANCET of April 21st, p. 1150, as to the making of "humanised" milk the following directions for making artificial human milk are taken from Playfair's "Science and Practice of Midwifery": "Take half a pint of skimmed milk, heat it to about 96° F., and put into the warmed milk a piece of rennet about an inch square (or Clarke's essence of rennet may be used). Set the milk in the fender or over a lamp until it is quite warm. When it is set remove the rennet, break up the curd quite small with a knife and let it stand for ten minutes or a quarter of an hour, when the curd will sink. Now pour the whey into a saucepan and boil it up quickly. Measure one-third of a pint of this whey and dissolve in it, when hot, 110 grs. of milk sugar. When this one-third of a pint of whey is cold, add to it two thirds of a pint of new milk, and two teaspoonfuls of cream, and stir. The food should be made fresh every 12 hours and warmed as required. The piece of rennet when taken out can be kept in an egg-cup, and used for ten days or a fortnight. It is advisable during the first month to use rather more than one-third of a pint of whey, as the milk is apt to be rather too rich for a newly-born child." I am, Sirs, yours faithfully,

JOHN E. H. PARSONS.

Shipton-under-Wychwood, Oxford, April 23rd, 1906.

TWO OLD MEDICAL BOOKS.

A CORRESPONDENT writes: "I recently picked up in an old book shop the following two medical books: 1. '*Profodia Chirurgica*,' published by C. Corbett at Addison's Head and Richard Chandler at the Flower-de Luce, both without Temple Bar. 1732. The author's name does not appear and there is a long dedication to a Mr. Shipton. 2. 'Anatomical Plates of the Arteries of the Human Body.' These are stated to be accurately coloured and reduced from the Icones of Haller with concise explanation. The book is published by E Cox, St. Thomas's-street. 1808." The writer adds that the plates in the second book are very fine and that both books are well bound in leather, and he inquires if any reader can tell him their value.

THE THERAPEUTIC VALUE OF CHEWING GUM.

THE habit of chewing a resinous substance after meals as an aid to digestion is very prevalent in the United States of America and in Canada. The preparations in most demand are known under the names of "chewing gum," "pepine gum," and "pepine." The custom is not unknown among Eastern peoples; thus, in India betel nuts and areca nuts are mixed with lime and used in a similar manner. In a recent number of the *Bulletin des Sciences Pharmacologiques* Dr L. Meunier has given the results of an investigation into the physiological aspect of the chewing habit and has drawn attention to its value in therapeutics. As a result of masticating a piece of chewing gum containing a small proportion of alkali the flow of saliva is increased to five or six times the usual volume. Herein lies the therapeutic value of the habit in cases where the gastric juice is excessively acid and so hinders the digestion of starchy foods. The acid is partly neutralised by the saliva which is thereby enabled to convert the starch into soluble products. A number of patients were put on a diet of 60 grammes of bread and 250 cubic centimetres of water per meal for two consecutive days. A masticatory consisting of an aromatic resin was given after each meal on the second day only. The gastric liquid was analysed half an hour after each meal, when the amylolytic change was considered to be complete and the figures show that the masticatory had in all cases increased the quantity of soluble products produced from the starchy food. Allowing for the dilution of the gastric contents by the increased flow of saliva the figures obtained in ten cases showed a gain of from 30 to 40 per cent. in the soluble-starch products due to the use of a masticatory substance. Dr. Meunier has obtained satisfactory clinical results in all cases of hyperacidity treated by him during a year, which tends to show that the American custom of chewing gum, though based on empiricism, may be supported on scientific grounds. Dr. Meunier does not state the exact kind of resin which he employed, but mastic is a suitable substance for the purpose. It is the resin obtained from *Pistacia lentiscus*, a small tree growing in Scio and in other islands of the Grecian Archipelago, where the resin has been produced from very early ages. It is mentioned in the works of Dioscorides and Pliny. It occurs in small rounded tears, pale yellow in colour, with an agreeable aromatic odour and taste. When chewed it readily forms a tenacious mass which does not stick to the teeth and so can be retained in the mouth for a considerable time.

MEDICAL REFEREES TO INSURANCE COMPANIES.

To the Editors of THE LANCET.

SIRS,—May I through the medium of THE LANCET call attention to what I consider a pernicious practice on the part of some life assurance companies?—viz., in a small town with perhaps half a dozen medical practitioners one only holds the appointment of referee to a big insurance company. By this appointment he gets into touch with the other men's patients and the local agent spreads the fame and skill of "our doctor." This is touting, and touting of the worst sort. Perhaps those who have been victims to this system, like myself, will give their opinion on the question. In a small town—say, of 2000 or 3000 inhabitants—why not appoint all the medical men instead of one only? The latter plan would, I feel certain, tend to cause a better feeling among the profession and in the end would work well in the interest of the insurance companies. Thanking you in anticipation of your publishing this letter, I am, Sirs, yours faithfully,

April 24th, 1906. CYGNUS.

◆

C. B.—We agree with our correspondent that there is no necessity for such advertisement, as the patients on the books of the practice have been privately notified of the intending dissolution. At any rate, one insertion in the local papers would suffice.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), St. Mark's (2.30 P.M.).

SATURDAY (5th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (1st).—PATHOLOGICAL SOCIETY OF LONDON (St. Bartholomew's Hospital).—5 P.M. Prof. Klein: (1) Bacillus Equi; (2) Conveyance of Plague by Feeding.—Mr. F. A. Rose: Carcino sarcoma of Larynx.—Dr. Andrewes and Dr. Horder: Classification of Pathogenic Streptococci.

WEDNESDAY (2nd).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.)—8 P.M. Specimens will be shown by Dr. Lewers, Dr. McCann, Dr. Tate, and Dr. J. I. Parsons. Short Communication—Dr. Lewers: Three Cases of Epithelioma of the Vulva with History subsequent to Operation. Paper:—Dr. Herman: A Case showing (1) Uterine Contraction without Retraction; (2) Prolonged High Temperature of Nervous Origin.

URSDAY (3rd).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish square, W.).—8 P.M. Card Specimens will be shown by Mr. S. Stephenson, Mr. W. Roll, Mr. A. L. Whitehead, Mr. F. W. Edridge-Green, Mr. J. B. Lawford, Mr. L. V. Cargill, and Mr M. S. Mayou. 8.30 P.M. Papers:—Mr. J. Taylor and Mr T. Collins: Congenital Malformed Cystic Eye.—Mr. M. Davidson: Radium in the Treatment of Rodent Ulcer.—Mr. R. Pickard: Implantation Tumour of Iris.—Mr. Cargill and Mr. Mayou: Tuberculosis of Choroid.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 P.M. Discussion on Asthma (opened by Dr. E. F. Willoughby).

IDAY (4th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—8 30 P.M. Discussion on Influenza, its Varieties and Sequelæ.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos-street, Cavendish square, W.)—5.30 P.M. Pathological Meeting Specimens will be shown by Dr. E. C. Mackay, Dr. J. P. Parkinson, Dr. L. S. Dudgeon, Dr. E. Cautley, Dr. F. Langmead, Dr. G. Carpenter, Dr. J. G. Emanuel (Birmingham), Dr. E. Hobhouse (Brighton), Mr. G. Pernet, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ONDAY (30th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—12.15 P.M. Mr. Baldwin: Practical Surgery. 2 P.M. Dr. Arthur: Skiagraphy. 2.15 P.M. Medical and Surgical Clinics. 4 P.M. Mr. Dunn: Ophthalmology.

CHARING CROSS HOSPITAL.—4 P.M. Dr. Galloway: Demonstration of Dermatological Cases (Post Graduate Course.)

UESDAY (1st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. H. Campbell: Clinique. (Medical.) 5 15 P.M. Sir Lauder Brunton: A Demonstration of Apparatus for Measuring the Blood Pressure in Man.

POST GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.)—11.30 A.M. Dr. H. Wright: Bacteriology. 2.15 P.M. Medical and Surgical Clinics.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen square, Bloomsbury, W.C.)—3.30 P.M. Clinical Lecture:—Dr. Batten: Ataxia in Childhood.

ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester square, W.C.)—5 P.M. Exhibition of Microscopic Specimens. Address:—Prof. G. S. Woodhead.

WEDNESDAY (2nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Mr. J. Cantlie: Clinique. (Surgical) 5.15 P.M. Lecture:—Dr. G. E. Herman: The Prevention of Difficult Labour.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M. Dr. H. Wright: Clinical Examination of Blood and Urine. 2.15 P.M. Medical and Surgical Clinics. 3 P.M. Mr. Bidwell: Intestinal Surgery.

UNIVERSITY COLLEGE HOSPITAL (Gower-street, W.C.)—4 P.M. Clinical Lecture:—Dr. F. T. Roberts: The Physical Examination of the Heart and Great Vessels.

THURSDAY (3rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.)—4 P.M. Mr. Hutchinson: Clinique (Surgical). 5.15 P.M. Lecture:—Mr. A. H. Tubby: Surgical Diseases of Children.

POST GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—11.30 A.M. Dr. H. Wright: Bacteriology. 12.15 P.M. Mr. Baldwin: Practical Surgery. 2 P.M. Dr. Arthur: Skiagraphy. 2.15 P.M. Medical and Surgical Clinics. 4 P.M. Mr. Dunn: Ophthalmology.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.)—5 P.M. Mr. P. C. Mitchell: The Digestive Tract in Birds and Mammals (Lecture II.)

CHARING CROSS HOSPITAL.—4 P.M. Dr. Murray: Demonstration of Medical Cases (Post Graduate Course.)

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn road, W.C.)—8 P.M. Clinical Evening.

FRIDAY (4th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Dr. H. Tilley: Clinique. (Throat)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.)—11.30 A.M. Dr. H. Wright: Bacteriology. 2.15 P.M. Medical and Surgical Clinics. 3 P.M. Mr. Bidwell: Intestinal Surgery.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.)—3.30 P.M. Clinical Lecture:—Dr. Batten: Infantile Hemiplegia.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-

tion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the *following* newspapers have been received:—*Standard, Bolton Chronicle, Manchester City News, Spalding Free Press, Andover Advertiser, Evening News (Portsmouth), Leamington Spa Courier, Herefordshire Mercury, Western Mail (Cardiff), Westminster Gazette, Dublin Weekly Times, Liverpool Post and Mercury, Surrey Advertiser, Literary Digest (New York), Scientific American, Daily Chronicle, Irish Times, Morning Leader, Daily News, &c.*

Communications, Letters, &c., have been received from—

A.—Dr. B. Anningson, Cambridge; Dr. G. Ainsley, Bad Schinznach, Switzerland; Dr. Anslow Alabone, Lond.

B.—Mr. J. W. Benson, Lond.; Dr. G. B. Buchanan, Stirling; Mr. H. A. Bridgman, Southampton; Messrs. Burton, Goldsmith, and Co., Lond.; *Birmingham Daily Post*, Manager of; Dr. R. Browne-Carthew, Biarritz; T. B. Browne, Ltd., Lond.; Dr. A. G. Barrs, Leeds; Mr. A. E. Braid, Lond.; Major A. L. Borradaile, R.A.M.C., Trawsfynydd; Messrs. Battle and Co., Paris.

C.—Mr. J. G. Carruthers, Lond.; Messrs. Candy and Co., Lond.; Messrs. Cole and Co., Lond.; Mr. A. P. Coker, Gisborne, New Zealand; C. A. C.; Coventry Hospital, Secretary of; Messrs. E. Cook and Co., Lond; Mr. F. W. Clarke, Chorlton-cum-Hardy; Mr. J. W. Astley Cooper, Cockermouth.

D.—Mr. L. Campbell Davys, Llandovery; Devon and Exeter Medico-Chirurgical Society, Secretary of; Messrs. W. Dawson and Sons, Lond.

E.—Dr. E. J. Elliot, Oxford; Mr. A. R. Elliott, New York; Messrs. Eames and Keys, Lond.; Dr. O. Eichholz, Lond.

F.—Dr. A. W. Falconer, Bradford; Mr. H. J. Fern, Cork; Messrs. Fussell and Co., Lond.

G.—Mr. Arthur Goulston, Heavitree; Messrs. Gordon and Gotch, Lond.; Dr. Alfred Greenwood, Blackburn.

H.—Mr. J. Harris, Lond.; Messrs. Hendry and Pattison, Lond.; Dr. E. Hull, Lond.; Dr. John T. Hewetson, Birmingham; Dr. Alfred Hill, Freshwater Bay; Mr. T. Hawksley, Lond.; Messrs. P. Harris and Co., Birmingham; Hants County Asylum, Fareham, Secretary of; Dr. W. E. Heilborn, Bradford; Mr. N. G. Horner, Lond.; Huddersfield, The Mayor of; Horspool Natural Voice Academy, Lond., Secretary of.

I.—Messrs. Isaacs and Co., Lond.; Messrs. Ingram and Royle, Lond.

J.—Sir Alfred Jones, Liverpool; Mr. R. F. Jowers, Brighton.

K.—Mr. W. M. Knipe, Worcester; Messrs. Knoll and Co., Lond.; Dr. R. Knox, Lond.; Kent and Canterbury Hospital, Secretary of; Messrs. R. A. Knight and Co., Lond.

L.—Mr. L. F. Leslie, Evesham; Dr. G. D. Laing, Lond.; Messrs. Longmans, Green, and Co., Lond.; Dr. F. Langmead, Lond.; Dr. Robert R. Leathem, Belfast; Low's Handbook to the Charities of London, Editor of; Mr. E. P. Leavy, Geraldton, Queensland; Lennox Chemical Co., Cleveland, U.S.A.; Mr. T. D. Luke, Edinburgh.

M.—Mr. J. M. Mangan, Ennis; Mr. H. W. Marshall, Manchester; Medical Supply Association, Lond., Secretary of; Messrs. C. Mitchell and Co., Lond.; Mr. E. C. Mulligan, Foxford; Dr. H. T. Morgan, Lond.; Dr. George S. Middleton, Glasgow; Mr. E. C. D. Milsom, Ipswich; Dr. T. K. Monro, Glasgow; Miss MacRobert, Lond.; Messrs. Morrison, Ingram, and Co., Manchester; Dr. A. S. Morton, Lond.; Dr. G. S. McKay, Wetherby.

N.—Newcastle-on-Tyne Asylum, Clerk to the; Mr. W. G. Nash, Bedford; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

O.—Oldham Infirmary, Secretary of.

P.—Mr. Y. J. Pentland, Edinburgh; Messrs. Peacock and Hadley, Lond.

R.—Mr. R. Redpath, Newcastle-on-Tyne; Royal Albert Hospital, Devonport, House Steward of; Rotunda Hospital, Dublin, Secretary of; Messrs. E. J. Reid and Co., Lond.; Messrs. Raphael and Co., Lond.

S.—Dr. G. F. D. Smith, Lond.; Society of Apothecaries of London, Secretary of; Colonel W. F. Stevenson, C.B., Jersey; Sheffield Union, Clerk to the; Sheffield Royal Hospital, Secretary of; South Devon and East Cornwall Hospital, Plymouth, Secretary of; Scholastic, Clerical, &c., Association, Lond.; Swansea General Hospital, Secretary of; Dr. H. Batty Shaw, Lond.; Mr. F. Wallis Stoddart, Bristol; Dr. J. Pollock Simpson, Lond.; St. Thomas's Hospital, Lond., Secretary of.

T.—T. B. G.

W.—Dr. J. R. Williamson, Bhandara, India; Dr. Arnold H. Watkins, Kimberley; Western General Dispensary, Lond., Secretary of; West Riding Asylum, Burley-in-Wharfedale; Messrs. F. Williams and Co., Lond.; W., Ivybridge.

Y.—Dr. R. A. Yeld, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. W. D. Anderson, Ballachulish; A. L.; A. R. F. E.; A. T. G.; A. A. C., Eltham; A. T.; A. C.; A. W. D.

B.—Dr. W. M. Brown, Crewe; Dr. F. T. Bond, Gloucester; Mr. Peyton Beale, Lond.; Mr. W. G. Bott, Lond.; Messrs. J. H. Booty and Son, Lond.; Mr. W. G. Burcombe, Lincoln; Mr. F. E. Bennett, Margate.

C.—Dr. P. J. Cammidge, Lond.; Messrs. S. Clarke and Co., Lond.; Messrs. Callard and Bowser, Lond.; Messrs. W. Carling and Co., Hitchin; Dr. H. W. J. Cook, Sale, Australia; C. W.; Miss S. Campbell, Ajmere, India; Mr. A. W. S. Curties, Great Chart; Messrs. T. Cook and Son, Rangoon; Cheltenham General Hospital, Secretary of; C. M. L.; Messrs. Cornish Bros., Birmingham.

D.—Dr. A. B. dos Remedios, Lourenço Marques; Messrs. J. Defries and Son, Lond.; Mrs. Darkes, Malvern; Derbyshire Infirmary, Secretary of; D. M.

E.—E. S. R.

F.—Mr. J. Fitzgerald, Queenstown; Mr. M. F. Fletcher, Grantham; Mrs. Forster, Christon Bank; F. L. K.; F. V.; F. M.

G.—Dr. R. Griffiths, Netherton; Mr. H. Bellamy Gardner, Lond.

H.—Mr. W. P. Hartley, Aintree; Dr. W. Hunter, Lond.; Messrs. Haasenstein and Vogler, Cologne; Mr. J. Heywood, Manchester; Halifax Royal Infirmary, Secretary of; H. F. C. M.; Messrs. W. Hollier and Co., Dorking.

J.—Mr. Y. M. Jones-Humphreys, Cemmaes; J. F. S.; J. F. W.; J. H., Lond.; Mr. B. S. Jones, Downham Market.

K.—Dr. W. Kirk, Ichang, China; Knighton Union, Clerk of; K. W. J.; Messrs. Kilner Bros., Lond.

L.—Mr. H. K. Lewis, Lond.; Dr. W. E. Lee, Lond.; L. F. L.; Leicester House, Brighton; Locum, Steeple Claydon; Captain F. W. Lambelle, R.A.M.C., Edinburgh; London Association of Nurses, Secretary of; Mr. H. Le Soudier, Paris.

M.—Dr. A. McLachlan, Beauly; Manchester Medical Agency; Professor Howard Marsh, Cambridge; Montrose Royal Asylum, Clerk to the; Mr. J. F. McClean, Constantinople; M. M. M., Lond.; Mr. F. H. Maberly, Birmingham; Dr. H. McKay, Bishop Auckland; Messrs. J. Menzies and Co., Edinburgh; Mysore Government, Bangalore, India, Senior Surgeon to the; Messrs. Z. P. Maruya and Co., Tokyo; Mr. B. N. Molyneux, Walsham-le-Willows; Medicus, Newcastle-under-Lyme; M.R.C.S., Lond.; Medicus, Stroud Green.

N.—Nottingham General Hospital, Secretary of.

O.—Owner, Bexhill.

P.—Miss M. Parkington, Eastbourne; Public Health Department, Cairo, Director-General of.

Q.—Mrs. Quinn, Clevedon; Messrs. Quibell Bros, Newark.

R.—R. W. J.; Mr. Reid, Ogmore Vale.

S.—Miss M. E. Smith, Redruth; Messrs. Spiers and Pond, Lond.; Selected London Properties, Secretary of; Miss Shepherd, Lond.; Mr. A. Snowdon, Hutton Rudby; Professor R. Saundby, Birmingham; Messrs. Savory and Moore, Lond.

T.—Mr. J. H. Thomas, Sheffield; T. S. E.; Dr. J. Taylor, Glasgow; Mr. J. F. Treston, Ballindine; Mr. J. Thin, Edinburgh.

W.—Mr. H. Wallis, Babbacombe; Mr. E. K. Williams, Pensnett; West London Post-Graduate College, Secretary of; W. A. J.; Mr. J. H. White, Workington; Professor Woods Hutchinson, Arrowhead, U.S.A.; W. M. K.; Mr. S. F. Walker, Bath; W. C.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements *on* pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent *to the Office* in reply *to* Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or *Subscriptions* should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and *other* Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnieres, Paris.

The Oliver-Sharpey Lectures

ON

THE BEARING OF METABOLISM EXPERIMENTS UPON THE TREATMENT OF SOME DISEASES.

Delivered before the Royal College of Physicians of London on April 3rd and 5th, 1906,

BY EDMUND I. SPRIGGS, M.D. LOND.,
F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE VICTORIA HOSPITAL FOR CHILDREN.

LECTURE II.[1]

Delivered on April 5th.

FEVER.

MR. PRESIDENT AND FELLOWS,—The treatment of fever is of the greatest importance. Such cases form a large part of medical practice. They are, moreover, in the majority of instances capable of recovery and the course of the disease may be profoundly modified by rational treatment. That a disturbance of metabolism is a prominent feature is obvious to every observer. An investigation into the nutrition of patients suffering from fever shows at once that a great increase in the excretion of nitrogen in the urine is present as compared with that of a healthy individual on the same diet. This phenomenon may begin early in the disease, even before the pyrexia, but usually does not, and it reaches its maximum much later, often after the crisis. Naunyn,[2] for instance, found on the tenth day that a patient was excreting 10·7 grammes of urea, on the eleventh day the pyrexia subsided and 45·4 grammes were excreted, and on the next day 91·9 grammes. In another case the fever was falling on the twelfth day and the excretion was 54·4 grammes, on the thirteenth 54 grammes, and on the 14th, the day of disappearance of the pyrexia, 90·4 grammes. Garratt found in scarlet fever and measles, however, that the excretion of urea reaches its maximum usually before the temperature returns to normal. When the excretion occurs late it is not due to retention of nitrogenous matter, because analysis of the tissues shows that there is no excess of urea in patients dead from fevers. Also, urea administered to febrile dogs is quantitatively excreted by them. The nitrogen arises from the breakdown of proteid tissue, chiefly muscle. This is shown by the facts that there is a corresponding increase in the output of potassium salts, sulphuric acid, and neutral sulphur and creatinin. The amount of breakdown is much greater than ever occurs with muscular work, and, indeed, in any circumstances except the taking of large quantities of proteid food. It is not due to starvation, for the excretion of nitrogen and the loss of weight is much greater in a fever patient than in a healthy man on the same diet.[3] A similar excretion of nitrogen, though less in degree, is observed after the administration of certain poisons, such as phosphorus, and in conditions of deficient oxidation.

It is important to know the cause of this breakdown of tissue and the possibility of its being due directly to the pyrexia suggests itself. Hot baths, sufficiently prolonged to cause a rise of temperature, give rise to increased oxidation, as shown by the respiratory exchange, and also to a rise in the amount of urea in the urine, occurring on the following and the third day. Predtetschenki found that the carbon dioxide might be even 70 per cent. above normal, and the nitrogen excretion from 50 to 100 per cent. (Speck, Winternitz). Muscular exertion, if carried on under conditions leading to a rise of temperature, such as in unsuitably clothed soldiers marching in hot weather, may also cause a delayed increase in the urea (Zuntz und Schumburg, Speck). But the facts that (1) the excretion of nitrogen in fever is not proportional to the pyrexia and bears no constant time relation to it, and (2) that septic infection may cause a similar rise in the nitrogen without any pyrexia (Simanowsky) are against this view that the pyrexia is the sole cause of the nitrogenous breakdown.

Again, is the tissue breakdown causally connected with increased oxidation? The determination of the oxidation going on has been made by many observers through estimations of the oxygen used and the carbon dioxide given out. The results show that, on the whole, more oxygen is generally used;[4] the excess is usually not more than 10 per cent. and seldom more than 20 per cent. above the normal (Lœwi, Langlois, Babák); there may be no increase in oxidation, and when it does occur it shows no parallelism with the excretion of nitrogen, or with the height of the temperature. Calorimetric experiments on man by Nebelthau showed that there may be an increased production of heat but the prominent factor is the inconstancy of the production. The variability and lack of decision of these results suggest that the larger use of oxygen in fever which may take place is not due to the breakdown of nitrogenous tissue at all, but to other causes, one of which is the muscular movement resulting from the restlessness which accompanies the febrile state. The patient is uncomfortable and slight movements are constantly being executed. We have seen in discussing the question of the effect of rest on metabolism how definite an effect upon the oxidation processes even inappreciable activities occasion. Atwater's subjects produced more carbon dioxide when their sleep was restless. That muscular activity is a cause of the greater use of oxygen is also supported by the observation of Zuntz that the consumption of oxygen is normal in curarised animals rendered septicæmic, since in this case no impulses can reach the muscles and cause them to contract. The non-muscular tissues are also believed to take part in the increased oxidation of fever.[5] It appears, therefore, that the breakdown of nitrogenous tissue is in some cases independent of any increase in the oxygen used, and it is probably due to the action of poisonous substances produced from the micro-organisms which give rise to the pathological process. The pyrexia is a concomitant effect of the poison acting upon the mechanism which regulates the temperature in such a way that the balance between heat production and heat loss is no longer accurately maintained. The loss is usually relatively diminished as compared with the production.

We may sum up then by saying that so far as the evidence at present leads us the products of bacterial infection cause: (1) a disturbance of the heat regulatory mechanism, resulting in instability of regulation; a febrile temperature is more easily altered by hot or cold baths than the normal; (2) a disintegration of the nitrogenous tissues, especially the muscles; and (3) the pyrexial condition is usually accompanied by increased oxidation. This is probably chiefly due to subconscious muscular movements, brought about reflexly from subjective sensations of discomfort.

We have now to ask how far and in what way these processes can be modified by treatment. It is obvious that the first thing to do is to attack the cause by means of antitoxins or any anti-bacterial substances that may be available. In addition to this method, or failing it, every means should be taken to make the patient comfortable, because the more at ease he is the less will be the reflex involuntary movements which may make a considerable demand upon his store of available energy and which in so doing shorten the length of time during which he will be able to resist the infection. Also, we can supply food to make up for energy lost. Although we usually cannot remove the cause of the fever we can diminish some of its effects by adopting measures for the reduction of the temperature. If the temperature be not dangerously high the condition of the patient as to restlessness is a useful guide in considering whether bathing or sponging should be carried out or not in order to increase the heat loss and cause a fall of temperature.

Effect of baths in fever.—The effect of cool baths upon the metabolism is shown in the results of Sassetzky (1883).[6] Nine cases of typhoid fever were observed. In each case a three-day period during which baths were administered was compared with a three-day period without baths and with the same length of time, about four weeks, after the subsidence of fever in eight of the cases. The food during the observations was milk and water. During the bath periods four baths a day were given at a temperature of 22·5° C. The patient sat up to the neck in the water and water was poured on to the head. The beneficial effects of the treatment were distinctly shown in the nitrogenous metabolism. If we take the average of the figures for all the bath periods we arrive at the result that the excretion of nitrogen was less in each case during the bath periods and the loss of nitrogen over the intake was less by 2·7 grammes per day than in the periods without the baths. This is not an average of conflicting figures, for the same effect was seen in each case. 2·7 grammes of nitrogen are equivalent to 16·8 grammes of proteid and to about 89 grammes of flesh. This comes to 267 grammes of flesh, or over nine ounces in the three days. We may assume that the fat in the body would also be spared to a considerable degree. The analysis of the fæces showed that the nitrogen excreted in this way was also less and therefore a more perfect absorption of the proteid of the milk took place during the bath period. The same observer gave quinine in three cases for a similar period and sodium salicylate in two cases for two-day periods. These drugs caused an improvement in the same way. This was more marked with quinine but in neither case was it as great as in the bath observations. Deucher[7] also found that antipyretics, which lower the temperature in typhoid fever, also lessened the loss of nitrogen. Actual nitrogenous equilibrium, however, could not be attained.

---

[1] Lecture I. was published in THE LANCET of April 28th, 1906, p. 1153.

[6] A Digest of Metabolism Experiments, p. 209; see also Virchow's Archiv, 94, p. 533.

These observations seem to show that tepid or cold baths exert an influence upon the proteid breakdown in the direction of lessening it. The amount of milk supplied was two litres or more, which would give a caloric value of 1400 calories; since this would barely supply the needs, the body might have been calling upon its own proteid for energy needs for muscular movement, secretion, &c. We cannot exclude, therefore, the possibility that the baths really produced their effect upon metabolism by diminishing the subconscious movements with the fall of temperature and thus lessening the call upon the body tissue, and this might explain the results without calling in any effect of the treatment upon the direct poisoning action of the toxins on the proteid constituents of the body. Indeed, we know that cold baths do not shorten the period of the disease in typhoid fever and may conclude from this that they do not intrinsically affect the bacterial process.

In connexion with the question of baths in typhoid fever it is of interest to compare a series of metabolism observations made for other purposes with a series in which baths were given. In the "Digest of Metabolism Experiments," if we compare the figures of the excess of nitrogen in the urine over the intake in the experiments of Diakonov (1890), undertaken to investigate the action of alcohol, with those of Matzkevich (1890), undertaken to ascertain the effects of copious water-drinking but in which each patient received two or three baths per day, we see a marked difference. Each worker observed several cases; the diets are not identical but roughly alike, the amounts of nitrogenous food being similar; but whether we look at the periods with or without alcohol, or with plentiful or restricted water, the most noticeable point is that in Matzkevich's cases, in which baths were used; the loss of nitrogen is usually several grammes a day less than in those of Diakonov. I need hardly remind you that there is strong evidence of a statistical nature that the prognosis in this disease is better under the bath treatment. This beneficial result may be ascribed to the fall of temperature produced. I have already mentioned that experiments on animals have shown that the resistance to a state of inanition is much lessened when the temperature is raised, and though, as we shall see, much may be done in the direction of supplying food to such cases, in most instances we are dealing, nevertheless, with a condition of partial inanition.

Food in fever.—Coming now to the problem of the feeding of fever patients it is obvious from what we have seen of the pathology of this condition that in circumstances in which the proteid tissues of the body are being continually broken down by the action of a poison, while at the same time the needs of the body as shown by the oxidation—that is to say, the ordinary running expenses—are commonly greater than usual, it is desirable to supply to the organism what energy we can, provided that the course of the disease is not thereby adversely influenced. "One of the dangers of prolonged fever is the general failure seen in starved animals."[8]

The absorption of food.—Huppert (1869) found but little deficiency in the absorption of nitrogen in recurrent fever.[9] The first question to be answered is, If food be given, is it absorbed from the intestine? Abramovitch (1888) in seven cases of croupous pneumonia found that the absorption of proteid from bread and milk was sufficiently good during the fever as compared with that after the crisis and in convalescence. It is true that he states the opposite but an examination of the figures shows no difference great enough to have any bearing upon the point at issue. From five to eight grammes of nitrogen were given per day. Pipping[10] (1891) found that in diphtheria with moderate fever in children on a mixed diet the absorption was as good as in health unless the temperature was exceptionally high. Von Noorden found absorption good in two cases of pneumonia and in one of tuberculosis, both for proteid and fat. Hoesslin (1882) in 19 cases of typhoid fever found that the digestion and absorption of a mixed diet were, in respect to proteid, carbohydrate, and fat, very little inferior to those in health. These patients were suffering from diarrhœa which does not seem to affect the utilisation of the food unless it be excessive. Khadgi (1886) found that the assimilation of meat, bread, and milk was almost as good during typhoid fever as in convalescence. Tschernoff showed that the absorption of milk fat was almost normal; from 88 to 93 per cent. was used. We find, then, that in a number of fevers if food be introduced into the alimentary canal it is made use of. The point of difficulty is that the patient has no desire for it. Appetite is wanting because it depends upon the integrity of the stomach and this organ shares in the general depression of function of the whole body. The hydrochloric acid is usually deficient, though not commonly absent. Pepsin may generally be found to be present. Food introduced into the stomach is in most cases passed on into the intestine and though we should expect that in the absence of hydrochloric acid from the stomach the stimulus to the secretion of pancreatic juice would be wanting, nevertheless experiment shows that the nutriment is not usually discharged from the intestine. It does not, however, necessarily follow that it is made use of for purposes of nutrition because we might suppose that it is broken up by bacterial action and its energy lost to the body. The excretion of aromatic sulphates gives a guide to the putrefactive processes going on in the intestine and we find that these bodies are not necessarily increased in the urine in fevers, although this may be the case. The best answer to this doubt is that in fever it is possible to feed the patient so that the body weight is kept up in some cases and in others so that the loss is very much less than it otherwise would be. This fact proves that the food is utilised. There is, of course, no doubt that the putrefaction in the gut is often greater than normal in this condition and carbohydrate and fat may be to a considerable extent broken down into substances which would escape recognition in the analysis of the fæces. Any unabsorbed nitrogen, however, would be recognised as such, while in the putrefactive processes resulting in the formation of tryptophane and its aromatic derivatives it is possible that other amido-bodies formed can be absorbed and made use of, just as they generally are when the proteid is disintegrated by the action of the normal ferments, without an excess of bacterial growth.

In connexion with the question of digestive disturbances due to putrefaction we may notice that proteid is the food-stuff from which the aromatic portion of the molecule of the ethereal sulphates is derived and that consequently the determination of these substances in the urine only gives us information concerning the bacterial action upon proteid in the intestine. But it is important to know what foods favour or hinder this process. Analyses show that a rich diet of proteid with but little of other foodstuffs is likely to undergo more putrefaction than when abundance of carbohydrate is present. This is believed to be because from carbohydrates weak acids are produced which restrain the action of putrefying organisms. The addition of much fat, on the other hand, increases the ethereal sulphates in the urine. So that a diet of all three foodstuffs in the proportions generally used in health—that is, with only a moderate amount of proteid or of fat—is indicated when it is thought that the patient is suffering from the effects of harmful substances absorbed from the intestine. Constipation is favourable to excessive bacterial growth and the removal of this condition when present is often of more importance than the alteration of the diet.

The quantity and kind of food.—We must now inquire what information we may get from metabolism experiments as to the quantity of food which should be given in febrile states. The needs of the body are as great as, or greater than, usual and if possible it would be desirable to meet them with food. This is a counsel of perfection and in many cases will not be attained but, nevertheless, should always be aimed at. We have seen that in starvation, when the body is living upon its own tissues, about 25 calories per day are used for every kilogramme of body substance; fat people requiring somewhat less, since a good proportion of their weight consists of fat, and this does not undergo constant metabolic changes as does all the more living proteid tissue. We should endeavour therefore, unless there is reason to believe that the fever is likely to be of extremely short duration and the individual is well nourished, to give sufficient food to supply at least 25 calories per kilogramme of bodyweight. This is of the greater importance because, as we have already seen, the condition of inanition is far worse sustained with pyrexia. That it is possible to keep the weight from falling during fever is shown by the experiments of von Noorden in a case of typhoid fever. Some other cases quoted by him, such as those of phthisis and chronic sepsis, are less convincing as regards acute fevers. To expect to prevent the toxic breakdown of proteid by means of food is in most cases probably more than is reasonable, but it is essential to supply the energy which the body needs and thus to ward off the addition of inanition to the other dangers of the disease.

Fluid food has the advantage that it satisfies thirst but its energy value is correspondingly low. Three pints of milk contain about 1150 calories. In a man of 70 kilogrammes 25 calories per kilogramme come to 1750 calories. Milk calls forth less gastric juice than other proteid foods, but if it curds must be diluted, peptonised, or decalcified with sodium citrate, as suggested by Professor Wright. It is not within the scope of my subject to discuss the various ways in which the diet may be varied, except in so far as metabolic experiment is concerned. Has such observation shown that any foodstuff has an advantage? Since much proteid is being broken down it seems desirable, even if we do not hope to prevent the breakdown, to supply enough to replace it. An examination of the figures shows that this is not to be expected. In most recorded experiments the amount of proteid given is low, but in those in which it is not, nitrogen equilibrium is not usually attained. In those of Puritz (1893) a diet of over 2500 calories was given, amounting in some of the patients to more than 42 calories per kilogramme per day, and containing proteid corresponding from 20 to 26 grammes of nitrogen per day, and yet in the observations upon six cases of typhoid fever extending from nine to 27 days in the different cases, in none was nitrogenous equilibrium attained. We may therefore ask if there be any advantage in giving such large quantities of proteid food. The observations of Moraczewski[11] in 18 cases of pneumonia show that although nitrogenous equilibrium is not to be looked for, yet the loss of nitrogen from the body—i.e., the output minus the intake—may be much lessened by furnishing a plentiful supply of proteid. He also claims that convalescence is much shorter when this has been done. This we should expect, for the poorer the body is in proteid at the end of the fever the longer would the period of convalescence be. The same has been found to be the case in enteric fever. One way of furnishing a fair quantity of proteid is to add protene or plasmon to the milk.[12]

With the object in view of ensuring that nourishment of a sufficient caloric value shall be provided, as much fat as can be taken without exciting distaste for food should be given. This quantity is not great. In addition to the fat in milk, that of cream and butter is of most value in fevers. One ounce of cream gives about 89 calories[13]; four ounces of milk about 95. So that a quarter of a pint of cream added to the day's feeds of milk adds 356 calories. Butter contains about twice as much fat as cream, and therefore two ounces of butter a day will add another 356 calories to the value, and this is likely to be nearly all absorbed. Hence a quarter of a pint of cream and two ounces of butter introduced in the milk, or upon bread, together add 712 calories to the value of the diet in an absorbable form. This is more than half the need of a woman of 50 kilogrammes, and even two ounces of cream and two of butter add over 500 calories. It is not so necessary to give fat to patients who have a large share of this substance in the body.

Carbohydrate should never be omitted from a diet unless, as in certain severe cases of diabetes, this may be necessary for a time. We have seen that it is very probable that it is the absence of this foodstuff which leads to the appearance of acetone and its congeners in the urine in inanition and other conditions, and there is reason to believe that proteid is broken down to furnish carbohydrate. The experiments of May on rabbits showed that dextrose has a considerable sparing power on proteid in fever just as in health, and that 25 per cent. of the nitrogenous output was diminished by giving dextrose. Moraczewski[14] and others have found the same to be true in man. Our object is to give carbohydrate and fat so as to insure that no proteid need be broken down to supply the energy needs of the body, since we cannot prevent proteid breakdown from toxic action. Starch is probably the best form in which to give these foods. Failure of the amylolysis in the intestine must be a very rare phenomenon and since this process takes place gradually the sugar is probably absorbed at once and the risk of fermentation is less than if a quantity of absorbable sugar is introduced at one time. Such forms of starch as arrowroot, or that in bread, or in biscuit eaten with the milk, are usually well taken. Neither carbohydrate nor fat makes demands upon the digestive activity of the stomach. Since we know, however, from the work of Pawlow that the appetite is much keener when gastric juice is called forth, it is often desirable, whatever the nature of the meal, to cause a flow of this secretion, and this may be done by the use of some form of meat extract, home-made or otherwise. No bulky foods should be used, or the patient will take an insufficient quantity.

Water must be abundantly supplied in all cases of fever. An estimation of its intake and output shows that a smaller proportion of it appears in the urine than in health, as is indeed obvious. The experiments of Matzkevich, already referred to,[15] show that water drinking carried to excess increases metabolism in typhoid fever. Some of his patients took as much as six litres of fluid altogether in the 24 hours. Eight series of exhaustive experiments were carried out and no harmful effect other than the above, which was not constant, was observed. Grandier[16] also found copious water drinking (from five to 13 litres) increases nitrogen loss somewhat. The absorption of food is much the same. The author says it improves secretion from the skin and advises it. The tissues contain more water in fevers, perhaps because the number of nitrogenous molecules is increased.

Typhoid fever.—The feeding of patients suffering from typhoid fever has a special interest apart from general considerations concerning metabolism, in that the intestine is ulcerated, and it has been the general custom to give the food, whatever it be, in fluid form. A growing school of opinion regards this as unnecessary and it adds materially to the difficulty of getting a sufficient amount of fuel into the body, a matter of great importance in this fever from the beginning owing to the prolonged period of partial inanition which is likely to ensue. Also, a fluid diet, usually milk, soon becomes distasteful. In the decision of this question copious clinical statistics must prove a prime factor but it is germane to our subject to see what metabolic observations have been made which throw light upon it. In a number of the Russian experiments referred to when we were discussing the assimilation in fever, bread was taken in quantity with milk and other fluid foods, and in some meat. In those of Hoesslin at Munich, published in 1882, such articles of diet as porridge, rice, and ham formed part of the ration.[17] The foods were chopped and given in frequent meals. He found that the temperature was not harmfully affected. The danger of inanition, he concludes, is a much greater one than that produced by a mixed diet and gastric disturbances and vomiting are much less likely to occur than with the same foodstuff time after time. The observations of Puritz were made upon six soldiers, lasting from five to 29 days in each case. I have mentioned above the sufficiency of the diet in these cases; it amounted to at least 42 calories per kilogramme and often more. Proteid was in excess, nearly three grammes per kilogramme per day, the diet consisting of meat, bread, and milk, with tea, coffee, and port wine. He reports that no albuminuria or rise of temperature was caused by the diet and no complications, relapse, or lengthening of the fever period were observed, that the patients were comfortable, and that the convalescence was shorter.

It is interesting to remember that it is possible that the changes in the tissue-lymph circulation described by Dr. George Oliver, the founder of these lectures, which follow a meal may possibly exert, both in disease and in health, a beneficial effect upon metabolism.

PULMONARY TUBERCULOSIS.

In pulmonary tuberculosis we are dealing with an infective process which may or may not be pyrexial. Suitable material must be furnished to the cells of the body (1) to enable them to provide energy for their usual needs; (2) to provide any extra energy they may require in opposing the bacillary growth and withstanding toxins; and (3) to replace any tissue which may be broken down by toxic action. In the pyrexial cases there is often in addition a want of appetite to deal with just as in the shorter fevers. In this condition the motor and secretory functions of the stomach have, nevertheless, been frequently found to be normal. With respect to the toxic breakdown we have seen that it occurs in other infections even without pyrexia. Duclaux[18] ascribes the loss of organic substance to the agency of a ferment-like substance of a tryptic nature derived from the bacillus. The wasting of pulmonary tuberculosis is not due to deficient absorption of food, for many analyses have shown that it is usually normal. For instance, in 1894 Blumenfeld and Spirig found that when from 84 to 168 grammes of fat were given in the form of butter and a mixture of olive oil and oleic acid assimilation was normal. Goodbody, Bardswell, and Chapman found that from 87 to 98 per cent. of the fat given in a mixed diet was utilised, a considerable quantity being given in the day, the averages in each period ranging from 123 to 231 grammes. Proteid is also well absorbed (Mitalesen, Mircoli and Soleri, Goodbody, Bardswell and Chapman, Ott, and older workers) except when a great excess is given, and so is carbohydrate.

Mircoli and Soleri[19] compared the needs of a phthisical patient with those of a normal man. The subject had lost 10 kilogrammes in a year and weighed 77 kilogrammes. The sputum contained a large number of bacilli. There was no pyrexia. A normal individual took a diet of 35 calories per kilogramme containing 14 grammes of nitrogen per day. But this did not suffice for the patient, who only maintained his weight and nitrogenous equilibrium when 50 calories per kilogramme were given and 29 grammes of nitrogen. Each was fed until he felt fully satisfied. He took then 30 per cent. more caloric value and 100 per cent. more proteid than the healthy man. They express the view that the excess of proteid is necessary owing to the direct action of the poison upon the tissues. On such a diet a little proteid was laid on Ott has also shown that even with complete rest a phthisical patient will not only lay on fat but tissue proteid.

I have already referred to a diet of 50 calories per kilogramme as one found essential to maintain equilibrium in a phthisical patient. Goodbody, Bardswell, and Chapman in their researches found that from 50 to 70 calories could be given with advantage. Taking the average, 60 calories, this comes to just over 4000 calories a day in a man of 68 kilogrammes. They found also, as we have seen in the case of normal metabolism, that an excessive diet is very much better borne by patients who are below their usual weight and that it must be relaxed when the weight has passed above the normal figure. If too much food be given, although some of it may be laid on for a time, intestinal and gastric disturbances set in, putrefaction takes place in the intestine to an excessive degree, as was shown by the more than doubling of aromatic sulphates in the urine, and distaste for food soon follows. It is interesting to note that a boy, aged 13 years, whose metabolism was investigated, took and assimilated 3500 calories per day; as his weight was 35 kilogrammes this is over 100 calories per kilogramme per day. A growing individual uses relatively more food, both on account of the growth and of the larger surface loss of heat relatively to mass, and also probably on account of greater activity. The amount of food taken per kilogramme by this boy approaches that used in the case of a woman undergoing a rest cure above referred to (Hale White and Spriggs) who was taking and assimilating well a diet of over 110 calories per kilogramme per day.

With regard to the constituents of the diet Goodbody, Bardswell, and Chapman recommend 120 grammes of proteid, 140 of fat, and 300 of carbohydrate as average figures for an adult. The amount of proteid here is moderate. In this respect we may ask ourselves whether in the light of the recent movement in the direction of diminishing proteid in ordinary diets we have sufficient evidence that such large quantities are necessary in phthisis, since extra work is thrown upon the digestive organs and the kidneys. I do not know whether careful experiments have been done in which the proteid has been replaced by a sufficient caloric equivalent of other food over a considerable period. That the output of nitrogen of the body can be diminished in tuberculosis as in health by carbohydrate and fat has been shown by Laufer, who found that sugar was much more efficient than an equivalent weight of fat and still more so if the caloric equivalents be given, as 94 grammes of sugar correspond to 50 of fat. A similar investigation was made by Bockarev (1893) who investigated the effect of adding malt extract to a liberal diet. From 50 to 100 grammes were given in milk daily. Dry malt extract contains 76 per cent. of maltose and 16 per cent. of dextrin. A teaspoonful containing four grammes gives about 16 calories and a tablespoonful 60 calories, almost as much as an egg.[20] Bockarev's figures show a slight proteid sparing effect such as is to be expected from the addition of a small amount of sugar to the food.

We have seen that a phthisical patient requires more proteid than an ordinary individual according to Mircoli and Soleri, in addition to a diet of greater fuel value. In one mode of treatment extra proteid has been supplied in the form of meat powder. Kurlev (1886) carried out experiments on five cases in which there was forced feeding by means of a stomach tube with a meat powder and milk, and the metabolism during the feeding was compared with the period before and after. Only two of his experiments are of real value, since in the remainder the patient had been fasting. As much as 52·6 grammes of nitrogen (i.e., 52·6 × 6·25 proteid) was given per day for three days. An enormous quantity of nitrogen was laid on in each of the cases. In the one quoted, for instance, 12·8 grammes per day. We may probably assume that their weights were below normal. The heaviest was 54 kilogrammes. Absorption was fair, 3·9 grammes of nitrogen appearing in the fæces. The caloric value of this diet was about 3510 calories. The patients put on weight, the appetite improved, their temperature fell, the dyspnœa, perspiration, cough, and expectoration were less, and sleep was better. Experience, however, shows that with such forced feeding the weight put on above the normal weight is usually lost again,[21] and also causes deterioration in health.

In the system known as zomotherapy the object is not so much to introduce a quantity of proteid into the body as that raw meat or raw meat juice shall be taken. Héricourt and Richet[22] have published some striking experiments upon dogs rendered tuberculous, which seem to show a marvellous effect from this treatment, those animals fed upon raw meat withstanding the infection, whilst others fed upon cooked meat or other food did not do so. It should be borne in mind that raw meat is the natural food of this animal. Beneficial results have, however, been reported with other animals. R. W. Philip in favourably commenting upon the results of this treatment in man[23] mentions a metabolism research conducted by Galbraith upon patients undergoing it. Food was given of a constant nitrogenous content, but for a period raw meat was substituted for other nitrogenous food. The retention of nitrogen was increased, also the amount of hæmoglobin rose above normal, these results being coincident with a general improvement in the condition of the patient.

The value of rest, as employed in the treatment of pyrexial phthisis, has been discussed under the heading of fever. In this disease, in which it is necessary to husband all the chemical resources of the body, the conclusions we have drawn from a consideration of the metabolic circumstances apply with force.

NEPHRITIS.

The object of the physician in treating diseases of the kidneys is to maintain the nutrition of the body while keeping the excretion of nitrogenous matter, of salts, and of fluid, at such a level as shall not act harmfully upon these organs. The number of metabolism experiments in cases of kidney disease has been great during the past few years and patients suffering from acute and parenchymatous nephritis and from granular kidney have been subjects of investigation.

Absorption of proteid.—The absorption of nitrogenous food is reported to be not so good as in health[24]; from 10 to 15 per cent. of the nitrogen taken escapes in the fæces. On examination of the figures of the above workers, however, it will be seen that the amount of nitrogen discharged daily in this way is seldom more than two grammes and often less than one. The high percentage reported is due to the fact that the quantities of proteid given were small and when we remember that even when no food is taken nitrogen is excreted by the bowel we see that the percentage test is not a fair one. In general the nitrogen in the fæces is normal or nearly so. Higher figures have been many times recorded[25] but are exceptional. In such cases there may be as much as five grammes of nitrogen in the fæces in the day. With diarrhœa, such as is not uncommon in kidney disease, there is naturally a greater loss from the bowel and this is usually a coincident symptom in those cases in which an increase in the loss is reported. In Butler and French's paper[26] in four out of the five days in which the fæcal nitrogen was more than two grammes there was excessive action of the bowels. It is clear that we have no means of distinguishing what part of the loss is truly unabsorbed proteid and what part is cellular and secretory detritus or even compensatory excretion by the gut. If such true excretion exist it is clear from the above results that it can only reach a useful figure when there is diarrhœa extending over a considerable period and even then there is the possibility that the nitrogen in the fæces has never been absorbed. In this case the same result would be more intelligently and less harmfully attained by giving a little less proteid in the food. There is more ammonia in the fæces in nephritic than in other diarrhœas, but I do not know that this points to excretion from the gut, for the more recent analyses show that ammonia is not in excess in the blood in these diseases.

The excretion of nitrogen.—In acute nephritis with suppression, partial or complete, of the urine the kidney temporarily does not secrete either water or solids and it is reasonable to give what nourishment can be taken in such forms as will throw no work on this organ at all. Fats and carbohydrates answer this requirement and should for a few days be supplied in the form of dextrin, dextrose, rice, cream, and butter (von Noorden). In the more chronic forms the excretion of nitrogenous material from the kidneys is variously reported upon. Bartels (1877) in granular kidney found that the excretion of urea was normal. Fleischer (1881) affirmed that in chronic as well as in acute Bright's disease there may be retention of nitrogen even to seven grammes per day. Von Noorden and Ritter found both in parenchymatous nephritis and in granular kidney that in some cases there was retention and in others nitrogenous equilibrium and showed that there is frequently an oscillation of excretion, normal periods alternating with periods of retention. A woman with granular kidney took 15·5 grammes of nitrogen per day in the food. The urine contained 20·1 grammes—that is, 4·6 grammes more than that taken in was given out. Four days later the condition was reversed and for five succeeding days she retained 4·9 grammes per day. Again, observation of Mann's figures[27] shows the same thing. A man on a diet containing 17·5 grammes of nitrogen for two days retained 0·5 gramme and for three subsequent days ten times this amount. Similar variations were observed in other patients. Emerson[28] noticed the same phenomenon, a periodic increase of the nitrogen, albumin, and the total quantity of the urine taking place. A comparison is suggested with the spontaneous diuresis which occurs from time to time in diabetes. It is evident that with these alternations to reckon with none but observations extending over several days can guide us. Müller[29] found that if more than nine or ten grammes of nitrogen per day were given there was liable to be retention. This observation is fully confirmed by other workers. For instance, Kornblum's figures show that a patient weighing 62 kilogrammes for 11 days on 13·9 grammes of nitrogen retained 1·3 grammes per day, but on a diet containing 15·3 grammes retained three grammes per day for four days. Emerson's figures also showed delayed excretion of nitrogen on adding eggs to a milk diet in parenchymatous nephritis. We have seen that in normal metabolism this does not usually occur. There seems to be no essential difference between chronic parenchymatous nephritis and granular kidney in this respect, except that the granular kidney can often gradually adapt itself and excrete a larger amount of nitrogen daily. The striking unanimity of experimental results makes it clear that in chronic diseases of the kidney a certain amount of nitrogenous food can be satisfactorily dealt with but that an increase is followed by an excretion which is much more delayed than in health—that is, by retention for a longer or shorter period. The quantity which the kidney does excrete is about nine or ten grammes of nitrogen or about 60 grammes of proteid. This is about the same amount that we have seen a healthy adult has been shown to be able to subsist on, together with other foods. It is contained in one and a half litres of milk, or two and a half pints. When more proteid is given and retention occurs this is not necessarily followed by uræmia; neither, when uræmia occurs, has there necessarily been a preceding retention. Butler and French's figures show well that during a period of subacute uræmia the excretion of nitrogen in the urine may remain fairly constant, as compared with the periods before and after. On the nitrogen balance there was a greater excretion than intake, but this was no doubt due to the fact that the boy during the attack of subacute uræmia took so little food—less than half a litre of milk—that he was living partly upon his own tissues.

Baginsky came to the conclusion that the kidneys of children with albuminuria did not excrete nitrogen as well as did those of children in health. This is no doubt true, but the amounts given by Baginsky were excessive. In one case he gave a child of 21·8 kilogrammes 12·5 grammes of nitrogen, which is more than 0·5 gramme per kilogramme. We know that children take proportionately more food than adults, because their surface is relatively greater and also they have to grow, but with such figures as those above it is not surprising that there was a retention of 1·6 grammes of nitrogen. It follows that in treating these complaints this limitation of excretion must be recognised and that from both directions. The diet should not contain much more than 70 grammes of proteid, of which about 60 will probably be absorbed, and it is clear that it should not contain much less, for the minimum necessary for the needs of the body lies not far below this figure. Secondly, not only should the average proteid content of the diet be low but it should be constantly so from day to day. Thirdly, according to Rosenberg it is advantageous to withhold occasionally proteid almost entirely from the diet for a day or two.

Allowance must be made, as we shall see shortly, if there is loss by albuminuria of appreciable amounts of proteid. Gumlich in 1892 found the proportion of the urea in the urinary constituents was a normal one, from 83 to 87 per cent. In some cases with accumulating œdema the proportion was somewhat less, even down to 72 per cent. Butler and French estimated the urea as well as the total nitrogen and the albumin and found, excluding the albumin, an average of the nitrogen in the form rice, and ham formed part of the ration.[17] The foods were chopped and given in frequent meals. He found that the temperature was not harmfully affected. The danger of inanition, he concludes, is a much greater one than that produced by a mixed diet and gastric disturbances and vomiting are much less likely to occur than with the same foodstuff time after time. The observations of Puritz were made upon six soldiers, lasting from five to 29 days in each case. I have mentioned above the sufficiency of the diet in these cases; it amounted to at least 42 calories per kilogramme and often more. Proteid was in excess, nearly three grammes per kilogramme per day, the diet consisting of meat, bread, and milk, with tea, coffee, and port wine. He reports that no albuminuria or rise of temperature was caused by the diet and no complications, relapse, or lengthening of the fever period were observed, that the patients were comfortable, and that the convalescence was shorter.

It is interesting to remember that it is possible that the changes in the tissue-lymph circulation described by Dr. George Oliver, the founder of these lectures, which follow a meal may possibly exert, both in disease and in health, a beneficial effect upon metabolism.

PULMONARY TUBERCULOSIS.

In pulmonary tuberculosis we are dealing with an infective process which may or may not be pyrexial. Suitable material must be furnished to the cells of the body (1) to enable them to provide energy for their usual needs; (2) to provide any extra energy they may require in opposing the bacillary growth and withstanding toxins; and (3) to replace any tissue which may be broken down by toxic action. In the pyrexial cases there is often in addition a want of appetite to deal with just as in the shorter fevers. In this condition the motor and secretory functions of the stomach have, nevertheless, been frequently found to be normal. With respect to the toxic breakdown we have seen that it occurs in other infections even without pyrexia. Duclaux[18] ascribes the loss of organic substance to the agency of a ferment-like substance of a tryptic nature derived from the bacillus. The wasting of pulmonary tuberculosis is not due to deficient absorption of food, for many analyses have shown that it is usually normal. For instance, in 1894 Blumenfeld and Spirig found that when from 84 to 168 grammes of fat were given in the form of butter and a mixture of olive oil and oleic acid assimilation was normal. Goodbody, Bardswell, and Chapman found that from 87 to 98 per cent. of the fat given in a mixed diet was utilised, a considerable quantity being given in the day, the averages in each period ranging from 123 to 231 grammes. Proteid is also well absorbed (Mitalesen, Mircoli and Soleri, Goodbody, Bardswell and Chapman, Ott, and older workers) except when a great excess is given, and so is carbohydrate.

Mircoli and Soleri[19] compared the needs of a phthisical patient with those of a normal man. The subject had lost 10 kilogrammes in a year and weighed 77 kilogrammes. The sputum contained a large number of bacilli. There was no pyrexia. A normal individual took a diet of 35 calories per kilogramme containing 14 grammes of nitrogen per day. But this did not suffice for the patient, who only maintained his weight and nitrogenous equilibrium when 50 calories per kilogramme were given and 29 grammes of nitrogen. Each was fed until he felt fully satisfied. He took then 30 per cent. more caloric value and 100 per cent. more proteid than the healthy man. They express the view that the excess of proteid is necessary owing to the direct action of the poison upon the tissues. On such a diet a little proteid was laid on Ott has also shown that even with complete rest a phthisical patient will not only lay on fat but tissue proteid.

I have already referred to a diet of 50 calories per kilogramme as one found essential to maintain equilibrium in a phthisical patient. Goodbody, Bardswell, and Chapman in their researches found that from 50 to 70 calories could be given with advantage. Taking the average, 60 calories, this comes to just over 4000 calories a day in a man of 68 kilogrammes. They found also, as we have seen in the case of normal metabolism, that an excessive diet is very much better borne by patients who are below their usual weight and that it must be relaxed when the weight has passed above the normal figure. If too much food be given, although some of it may be laid on for a time, intestinal and gastric disturbances set in, putrefaction takes place in the intestine to an excessive degree, as was shown by the more than doubling of aromatic sulphates in the urine, and distaste for food soon follows. It is interesting to note that a boy, aged 13 years, whose metabolism was investigated, took and assimilated 3500 calories per day; as his weight was 35 kilogrammes this is over 100 calories per kilogramme per day. A growing individual uses relatively more food, both on account of the growth and of the larger surface loss of heat relatively to mass, and also probably on account of greater activity. The amount of food taken per kilogramme by this boy approaches that used in the case of a woman undergoing a rest cure above referred to (Hale White and Spriggs) who was taking and assimilating well a diet of over 110 calories per kilogramme per day.

With regard to the constituents of the diet Goodbody, Bardswell, and Chapman recommend 120 grammes of proteid, 140 of fat, and 300 of carbohydrate as average figures for an adult. The amount of proteid here is moderate. In this respect we may ask ourselves whether in the light of the recent movement in the direction of diminishing proteid in ordinary diets we have sufficient evidence that such large quantities are necessary in phthisis, since extra work is thrown upon the digestive organs and the kidneys. I do not know whether careful experiments have been done in which the proteid has been replaced by a sufficient caloric equivalent of other food over a considerable period. That the output of nitrogen of the body can be diminished in tuberculosis as in health by carbohydrate and fat has been shown by Laufer, who found that sugar was much more efficient than an equivalent weight of fat and still more so if the caloric equivalents be given, as 94 grammes of sugar correspond to 50 of fat. A similar investigation was made by Bockarev (1893) who investigated the effect of adding malt extract to a liberal diet. From 50 to 100 grammes were given in milk daily. Dry malt extract contains 76 per cent. of maltose and 16 per cent. of dextrin. A teaspoonful containing four grammes gives about 16 calories and a tablespoonful 60 calories, almost as much as an egg.[20] Bockarev's figures show a slight proteid sparing effect such as is to be expected from the addition of a small amount of sugar to the food.

We have seen that a phthisical patient requires more proteid than an ordinary individual according to Mircoli and Soleri, in addition to a diet of greater fuel value. In one mode of treatment extra proteid has been supplied in the form of meat powder. Kurlev (1886) carried out experiments on five cases in which there was forced feeding by means of a stomach tube with a meat powder and milk, and the metabolism during the feeding was compared with the period before and after. Only two of his experiments are of real value, since in the remainder the patient had been fasting. As much as 52·6 grammes of nitrogen (i.e., 52·6 × 6·25 proteid) was given per day for three days. An enormous quantity of nitrogen was laid on in each of the cases. In the one quoted, for instance, 12·8 grammes per day. We may probably assume that their weights were below normal. The heaviest was 54 kilogrammes. Absorption was fair, 3·9 grammes of nitrogen appearing in the fæces. The caloric value of this diet was about 3510 calories. The patients put on weight, the appetite improved, their temperature fell, the dyspnœa, perspiration, cough, and expectoration were less, and sleep was better. Experience, however, shows that with such forced feeding the weight put on above the normal weight is usually lost again,[21] and also causes deterioration in health.

In the system known as zomotherapy the object is not so much to introduce a quantity of proteid into the body as that raw meat or raw meat juice shall be taken. Héricourt and Richet[22] have published some striking experiments upon dogs rendered tuberculous, which seem to show a marvellous effect from this treatment, those animals fed upon raw meat withstanding the infection, whilst others fed upon cooked meat or other food did not do so. It should be borne in mind that raw meat is the natural food of this animal. Beneficial results have, however, been reported with other animals. R. W. Philip in favourably commenting upon the results of this treatment in man[23] mentions a metabolism

Emerson. The period of observation was too short to give definite results, since in cases reported to have been benefited by this operation, results such as disappearance of albumin and casts have been delayed as long as a year. In a few weeks during which analyses were made the metabolism of nitrogen showed the usual features of subacute nephritis becoming chronic with oscillations of excretion. The patients reported that they felt much better and the excretion of albumin became less.

ELIMINATION OF NITROGEN BY THE SKIN.

Perspiration in health contains a small quantity of nitrogenous substances, of which over two-thirds is in the form of urea (Argutinsky). This quantity is increased by profuse sweating and as much as 0·76 gramme and even 1·36 grammes have been found in the day in a hot climate (Eijkmann, Java). Atwater found that the mean amount in 68 experiments with muscular work was 0·29 gramme of nitrogen. With conditions in which the proportion of urea and other non-proteid nitrogenous substances in the blood was increased we should expect that the quantity in the sweat would be larger. Strauss[37] has recently found that the proportion of nitrogenous substances which are neither proteid nor urea is greater in nephritic perspiration than in healthy blood serum and may, especially in uræmia, reach a similar value to that in the serum and serous effusions of nephritis. These observations strongly support the practice of producing sweating, as do actual metabolic experiments with baths of hot water or hot air.

BATHS.

Very many observations have been carried out as to the effect of baths upon metabolism in nephritis. Korkounov[38] found that the dropsy diminished and the weight with it. The diet was milk and for from three to five days two baths per day at 40° C. and of from 15 to 20 minutes' duration were given. At the same time nitrogen was retained in the body but an examination of the figures shows that this was probably because more milk was taken during the bath period, owing presumably to thirst induced by sweating. Evdomikov[39] found in acute parenchymatous nephritis that the absorption and excretion of nitrogen were definitely improved by sweating. This was induced by enclosing the subject in a rubber bag up to the neck. A blanket was wrapped round the bag and the sweating lasted from one and a half to two hours. Improvement also followed in a second case of nephritis and cirrhosis of the liver as regards absorption. Hot air baths lasting from 20 to 25 minutes from 40° to 60° C., on a mixed diet containing an excess of nitrogen (from 20 to 40 grammes) were also given by Garine in 1887 in two cases of acute interstitial nephritis. Here again the excretion of nitrogen was improved during the bath periods (five days) and for the five subsequent periods, during which analyses were carried out, as compared with five days before the baths.

WATER AND SODIUM CHLORIDE.

Since the constituents of urine are all dissolved the amount of water available is a matter of importance and it is desirable to get what information we can as to what quantities should be allowed.

We must remember that in kidney disease the blood usually contains a larger proportion of water than in health[40] but this appears to be due to poverty of proteid, while smaller molecules, such as salt ions and the non-proteid nitrogenous substances, of which urea forms from one-half to four-fifths, are usually increased.[41] Thus, since the osmotic pressure of a solution depends on the number of molecules and not upon their size such hydræmic blood may, and often does, have a greater osmotic value than normal blood. According to Strauss, to whom we owe much work upon this subject, there is a parallelism between the amount of these nitrogenous substances and the degree of œdema, though none is established with the quantity of urine excreted (Brunner) or with uræmia. Now it is clear that the accumulation of fluid in the tissues may be due to a loss of power of the excretion of water by the kidneys or to a retention of water by the tissues. In the former case the drinking of an extra quantity of water would lead to œdema and no increase in the urine. In the latter if water be held by the tissues owing to the osmotic pressure of these electrolytes and of the saline molecules, additional water taken would cause increased secretion of urine. Experiment shows that in the acute form of nephritis an addition of water increases the œdema usually and does not appear in the urine,[42] though some cases of nephritis after the infectious fevers with hæmaturia prove exceptions.

In parenchymatous nephritis many cases react to water by passing it in the urine. Only experiment can ascertain whether this be so or not in the individual instance. The presence of œdema seldom means inability on the part of the kidney to secrete more water. Hence, in the treatment of such cases when œdema supervenes it is desirable to add water to the daily diet and to find out whether it be excreted in the urine or not. If it be, this most valuable of all diuretics will enable a portion of the substances to be excreted, which by their osmotic pressure may be holding fluid in the tissues and causing the œdema. The experiments upon granular kidney with abundant urine show that additional water is usually excreted in the urine. But Kövesi and Rothschultz state the amount of solid constituents is not increased, that is, a more dilute urine is passed. Von Noorden has found that the granular kidney can secrete urine of a normal specific gravity if water be restricted, and he is an advocate of such restriction, holding that thirst arises from some undetermined cause, but that the satisfaction of it by drinking is harmful, especially to the vascular system.

We must remember, however, that the secretion of a dilute urine more nearly isotonic with the blood than normal urine involves less work on the part of the kidney cells.[43] Galleotti found that after the injection of sodium chloride into a dog the osmotic pressure of the blood was not normal for 46 hours and the work done by the kidney was exceedingly large, but that if the dog were given water to drink the same result was produced in half the time with half the expenditure of work. Again, in Bradford's experiments[44] when the total kidney tissue was much reduced, the animals secreted a large amount of dilute urine and, at the same time, the blood became more watery and contained more urea, a condition strikingly similar to that in granular kidney. The production of dilute urine in large quantity, therefore, in this disease is, as experiment would lead us to expect, the way in which solids can be removed from the blood with the least performance of work by the kidney. Indeed, Beddard's reference[45] to the experiments of Bradford and of Ribbert applies equally well to the case of granular kidney when he remarks that the "change in the character of the urine observed in these experiments is probably to be explained in the light of Galleotti's results as the effort of the reduced kidney substance to excrete the maximal amount of material with a minimal expenditure of energy." The fact that the granular kidney may be able to produce urine of a high specific gravity does not show that it is desirable to perform this experiment upon every case of the disease.

The harm which von Noorden supposes is done to the vascular system by dealing with large quantities of fluid is also somewhat problematical or its results would be more often seen in diabetes insipidus and mellitus, in which much more water is drunk and excreted than is usual in chronic disease of the kidney.

The metabolism of water in nephritis is closely connected with that of sodium chloride and many observers have ascribed the œdema and many of the symptoms of nephritis, including the terminal uræmia, to the non-elimination of salt. It is improbable in the light of many facts that the pathology is as simple as this, but from the point of view of treatment we may look at the metabolism of chlorides in this disease. The excretion of chlorides in nephritics may follow the normal course and be equal in amount to that taken in with the food. On the other hand, a large number of analyses have been made which show that this is frequently not so. Many conflicting results are probably due to the observations not having been sufficiently prolonged, for the excretion of chlorides often oscillates, and while for a time there may be less in the urine, later in the case the retention may be corrected by a larger excretion. Such oscillations are also characteristic of the excretion of water and nitrogen

of urea of 83 per cent. and this average did not vary appreciably during an uræmic attack. There were individual variations of from 71 to 94 per cent., such as are found in normal urines. It is probable that the methods used to estimate urea may include other amides. Von Jaksch[30] states that in many diseases, including those of the kidneys and typhoid fever, from 20 to 25 per cent. of the total nitrogen in the urine may be present in the form of amido-acids or allantoin. Perhaps any accumulation of disintegration products prevents the tissues from being able to build up proteid from the amido substances formed during digestion or, on the other hand, from oxidising the products of break-down to urea as completely as usual. These variations in the amount of urea are not such as could be recognised by the ordinary hypobromite method and it follows that the testing of urine by this method to find the percentage of urea is fallacious as a guide to the excretive capacity of the kidney. Such a test is only valuable when the whole day's urine is collected and its content of nitrogen compared with that of the food. In nephritis patients are usually kept on a low diet and therefore they excrete but little urea. In ordinary cases, not upon a proteid rich diet, the nitrogen of the urine, together with that in the fæces, equals that in the food.

ALBUMINURIA.

Albumin in the urine is a direct loss to the body of material which could be used, just as is sugar in diabetes. The quantity of proteid lost in this way is usually small but if it be considerable may lead to a diet, which would otherwise suffice, being deficient in proteid. If we exclude from consideration acute nephritis or an acute process temporarily superimposed upon a chronic one, we may lay down as a rule that it is more important to feed the patient than to get rid of the albumin in the urine. Von Noorden gave a patient with albuminuria for three weeks a diet of milk containing 15·2 grammes of nitrogen; the patient remained in nitrogenous equilibrium, excreting 1·3 grammes per day as albumin and 1·9 in the fæces, therefore using 12 grammes per day. On reducing the nitrogen in the food to 10 grammes, keeping the caloric value (32 calories per kilogramme) and the quantity of fluid constant, 1·1 was lost as albumin and 2·5 in the fæces, leaving 6·3 to be used; on this diet 8·3 grammes was the daily average in the urine and so two grammes were lost daily, or 66 grammes of flesh. If sufficient food be given, with due regard to the dangers of excess which we have discussed, nitrogenous equilibrium may be maintained with large losses of albumin. I have mentioned from nine to ten grammes of nitrogen as being a desirable upper limit in the diet of a chronic nephritic, about 60 grammes of proteid. When the patient is constantly excreting a considerable quantity of albumin, proteid must be cautiously added to this, raising the maximum to from 85 to 90 grammes.

The estimation of the percentage of albumin in a single specimen of urine is liable to fallacy, for the amount of albumin is not constant during the 24 hours. Nevertheless, if the whole day's urine be collected and the albumin estimated daily variations in the percentage of albumin may form a valuable guide to the progress of the case, as Emerson has shown,[31] more so, indeed, than the total quantity in the 24 hours. The actual amount of albumin in chronic nephritis, if it be constant, though of use, as we have seen, in constructing the diet, is of little prognostic value. Emerson's experiments upon metabolism in albuminuria showed that as a case becomes chronic the percentage of albumin tends to become regular.

Important results have been obtained by metabolic experiments comparing the effect of the amount and nature of the diet upon the albuminuria. The proteid in the urine is, in the main, body proteid derived from the blood serum, as shown by precipitin tests. Food proteids, such as egg albumin, beef proteid, and lactalbumin, may be found in the urine when these foods are taken, but only in small quantities. If, as appears probable, the food proteids are completely broken down in the intestine to non-proteid substances, to be subsequently built up again into body proteid, we should only expect food proteid to occur in the urine when some of it had been absorbed in an undigested form from the alimentary canal.

The effect of food upon albuminuria.—The evidence goes to show that in granular kidney the nature of the food makes but little difference to the albuminuria, if its amount be regulated by the above principles, and no definite relation is found between the albumin and the food if the observations be carried on for fairly long periods. In acute nephritis and acute exacerbations of chronic nephritis this is not so. A rise in the amount of proteid given is usually followed by a rise in the albuminuria. Emerson's observations upon acute and subacute cases made over considerable periods with determinations of the total nitrogen metabolism are of interest. He found a parallelism between the percentage of albumin and the temperature, both tending to rise with an unsuitable diet or with an increase in the inflammatory process or with exercise. The third important symptom going with these is a diminution in the quantity of the urine. The nature of the food was of greater importance than its amount—for instance, the same percentage of albumin as before was excreted in a case of amyloid disease when the milk was reduced by half, but a sweatbread sent up both the percentage and the temperature. Perhaps the liver was also diseased in this case. Even starvation did not affect the albumin percentage to any degree. Raw eggs given with a milk diet sent up the albumin but this is an unfair test, for the same may occur in health from direct absorption. In severe parenchymatous nephritis the albumin was lowest with milk and rose when other articles were added. Milk alone has the disadvantage that a greater amount of proteid than necessary is given if more than from two to two and a half pints be taken by the patient. But cream or sugar or arrowroot may be added to this quantity without giving more nitrogen and thus the caloric value be raised.

Actual metabolism experiments as to the effect of different meats in chronic nephritis have been made by several observers. Prior[32] found that the addition of boiled eggs to the diet did not increase the albumin in the urine, neither did raw eggs when consumed with other food, but only if taken alone—i.e., under conditions which cause albuminuria in health. Offer and Rosenqvist[33] found no difference between red and white meat. Pabst's experiments[34] were not, strictly speaking, metabolism experiments, but he found that mutton, beef, veal, lamb, or fowl produced no effect on the microscopical characters of the urine as regards the number and nature of the casts present when compared with milk of the same proteid content. Kaufmann and Mohr investigated two cases of chronic parenchymatous nephritis and three of granular kidney. For five-day periods they gave a diet of 200 grammes of bread, 100 grammes of potatoes, 100 grammes of butter, 500 grammes of soup, and 325 grammes of either beef or veal to compare the effect of red or white meat. In each case there was slight loss of nitrogen but the albuminuria and the œdema were less with the beef. These periods were rather short and the proportion of nitrogenous food was too high, from 15 to 20 grammes of nitrogen appearing in the urine. In another case excreting from 12 to 13 grammes of nitrogen in the urine no difference in metabolism could be detected between diets of constant nitrogen and caloric content supplied by means of milk, beef, veal, and milk again in five-day periods, one after the other. In older experiments, such as those of Gregoriev,[35] similar observations with milk and meat lead us to no definite results, because the amount of nitrogen in the different diets varied and the caloric value was often too low.

DIURETICS.

Since the urea in the blood has been found to be increased both in nephritis and in uræmia and since we know that this substance is an excellent diuretic, one would suppose that the administration of diuretics other than water would not be likely to produce much effect. Diuretin was given in the course of Emerson's experiments and was followed by an increase in the urine, which was more dilute, though the total albumin in the urine in the 24 hours was increased. Grünwald[36] also reports that diuretin causes the excretion of a more dilute urine, with less albumin.

DECAPSULATION.

The metabolism of two patients before and after decapsulation for acute parenchymatous nephritis was observed by

A PAPER ON

THE PATHOGENY OF DIABETES.

Read before the Section of Medicine at the Fifteenth International Congress of Medicine at Lisbon, April 19th to 26th, 1906,

BY F. W. PAVY, M.D. LOND., LL.D., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

BEFORE the pathogeny of diabetes mellitus can be satisfactorily dealt with it is requisite that we should have a right comprehension of the nature of the disease. Without a knowledge of the pathology of the disease, based upon a correct foundation, we cannot reasonably expect to be in a position profitably to enter into its pathogeny. For this reason it is necessary to give preliminary consideration to the conditions standing at the foundation of the disease. The outside features of the disease are conspicuous enough but the conditions existing within have been involved in much obscurity. Essentially the cardinal point presented is that carbohydrate which ought to pass to utilisation in the system flows off in the form of sugar with the urine. The reason of its doing so is obviously connected with faulty chemical action located in some part or other of the economy, and the great desideratum is a knowledge of the seat and nature of the error existing

Primarily, it may be asked, Whence comes the sugar that is found in the urine? Is it conveyed to the kidney in the blood and simply eliminated by the organ or is it formed within the kidney from some constituent of the blood that is circulating through it? Both sources appear, in different circumstances, to exist. Ordinarily, as in human diabetes, hyperglycæmia is antecedent to the glycosuria. The fault in this case lies with the abnormal presence of sugar in the circulatory system, the sugar flowing off with the urine in proportion to its existence in the blood. In phloridzin diabetes the sugar is evidently not derived from pre-existing free sugar in the blood; in other words, there is not the preliminary hyperglycæmia to give rise to the glycosuria. It seems as if through the influence of the phloridzin sugar is cleaved off from a constituent of the blood that contains it in a locked-up state whilst the blood is circulating through the kidney. Other instances present themselves in which it is evident that sugar is derivable from combined or locked-up sugar in the blood and the tissues. In human diabetes, as I have said, glycosuria is secondary to hyperglycæmia and the question is carried to the faulty action giving rise to the latter. There is a class of case in which the eliminated sugar is in a direct manner traceable to carbohydrate in the food ingested. Under the glycogenic theory it is considered that the carbohydrate of the food passes in the form of sugar through the circulatory system to the capillaries of the tissues, to be there oxidised and consumed, and the hyperglycæmia of diabetes is assigned either to an excessive influx into the circulation or to a deficient removal within the systemic capillaries. To this view of influx, transport, and removal I have contended there is the fatal objection that in proportion as sugar enters the circulation so it becomes manifest in the urine, its small molecular constitution leading to its escape with the urinary water in passing through the kidney. To keep sugar out of the urine it must be kept out of the general circulation, and this necessitates that the food carbohydrate should be dealt with by assimilation before the opportunity is afforded for its reaching the systemic blood. I have dwelt upon these matters in my recent work on "Carbohydrate Metabolism and Diabetes" (Churchill, London, 1906), and I there adduce evidence to show that at the seat of absorption in the alimentary canal the carbohydrate is assimilated by synthesis into proteid through the instrumentality of the lymphocytes of the villi, and by conversion into fat through the agency of the epithelial cells of the villi. The carbohydrate that may happen to escape being disposed of here, becomes conveyed as sugar by the portal vein to the liver, and checked in its further course by transmutation into glycogen. Thus the contents of the general circulation are guarded, as is noticeable in a state of health, against being influenced by the ingestion of carbohydrate food. Should the carbohydrate fail, as happens in diabetes, to be in this way assimilated it passes on as sugar into the general circulation and thence flows off with the urine. The difference, then, between health and "alimentary" diabetes is that in the one case carbohydrate is assimilated and prevented reaching the general circulation as sugar, whilst in the other it escapes being assimilated and, as a result, reaches the general circulation as sugar.

This brings us to the consideration of the operations concerned in the process of assimilation, as it is from their failure in being properly carried out that hyperglycæmia, and thence glycosuria, emanate. When assimilated by synthesis into proteid through the medium of the actively growing lymphocytes in the villi, the flow of which into the circulation constitutes the source of digestion lymphocytosis, sugar is put into a state to be free from liability of escape with the urine Locked up, probably as a side-chain, in a large molecule its retention within the confines of the circulation is secured, and at the same time it is in a position to be ready for detachment to meet the wants of the tissues just as happens in the case of oxygen as it exists in oxy-hæmoglobin. Synthesis or building up is now recognised as effected, like catalysis or breaking down, by the agency of enzyme action, and in this way the connexion of the pancreas with diabetes may be rationally explained. There is evidence to show that an internal secretion is derivable from the pancreas which is concerned in keeping the system exempt from the condition existing in diabetes. This internal secretion may be taken as probably contributing to the action that occurs in the construction of the bioplasm of the lymphocytes from the absorbed digestion products of the food. Enzymes, it has recently been learnt, are dual bodies, one portion being apparently of a proteid nature and losing its activity at the boiling temperature, whilst the other does not similarly lose the power belonging to it on being boiled. To the latter the name co-ferment or activator has been applied and it seems to hold an analogous position to the active agents that are obtained from the thyroid, suprarenal capsules, &c. The experiments detailed in my recently published work on "Carbohydrate Metabolism and Diabetes" already referred to point to a co-ferment-like body being yielded by the pancreas which aids in the synthetic process concerned in the linking on of sugar in the construction of proteid. Thus circumstanced, the pancreas, in relation to internal secretion, presents an alliance as regards its mode of action to the glandular structures that have been named. Under the view that has been outlined the connexion of the pancreas with diabetes is rendered intelligible. In the absence of the internal secretion, as after extirpation and in association with disease, the non-existence of the co-ferment concerned in the building up of carbohydrate into proteid would lead to failure of carbohydrate assimilation, and thence give rise to the condition met with in diabetes. What I have spoken of only touches defective assimilation through absence of proper enzymic power. Whether or not the linking on operation in the construction of proteid in the villi is related to that concerned in the production of glycogen in the liver it is impossible to say, but, as a matter of fact, the latter is as much the result of a building-up process as the former and it is possible in both instances that the issue may be brought about by the same instrumentality.

Another source of sugar in connexion with diabetes is the breaking down of complex molecules into which the sugar molecule has previously entered. Evidence is afforded of the occurrence of this phenomenon in advanced cases of diabetes where the power no longer exists of preventing the elimination of sugar by restriction from carbohydrate food. In these cases there is more or less active wasting and it may be assumed that through the influence of an abnormal enzymic agency there is a wrong katabolism or tissue disintegration proceeding which is attended with the liberation of sugar. It is in this class of case that other products of wrong retrograde metamorphosis present themselves to view—namely, β-oxybutyric and diacetic acids, and acetone. When the condition alluded to exists there is a two-fold source, of a contrasting nature, for the sugar. In the one the sugar met with is the issue of a defective anabolism or molecular building up and in the other, an abnormal katabolism or breaking down of molecules into which carbohydrate has been previously incorporated. The former corresponds with the "alimentary" form of the disease, the latter with the grave, or the "composite" form as I have styled it on account of both conditions existing together.

The point to be now considered is the question of in kidney disease, and the excretion of salt is usually, but not always, parallel to that of nitrogen. This variation explains those instances in which more chlorides appear in the urine than were in the food, as in a case observed by Halpern in which in 16 days the excess of chlorides in the urine was 208·69 grammes. A similar phenomenon is the delay in the excretion of added salt. A healthy individual excretes an extra dose of salt in from 28 to 48 hours, while in kidney disease the whole of the salt may not appear for some days. This is similar to what we have seen in the case of the nitrogenous substances.

Most striking are the cases with definite retention of salt, associated with œdema. This condition is usually found in acute nephritis and severe chronic parenchymatous cases, not so commonly in cases of granular kidney, except during exacerbations of a superimposed acute or subacute process, and also when the heart is failing. In cases of one-sided disease less salt has been found in the urine from the affected kidney. The two kidneys, however, do not always excrete the same amount of salts in health. The quantity of sodium chloride in the urine in 24 hours may be less than one gramme and Bing[46] has reported two cases of achloruria, in which hypersecretion in the stomach occurred, with vomiting of salt and water, a condition which he designates as one of chronic sodium chloride poisoning. This would certainly suggest failure of excretion. Apart from diarrhœa no increase in the fæces accompanies diminished excretion in the urine. The retention of chlorides is connected with œdema, and in some instances this relation is very marked. Diminishing the amount of food has been found to be followed by less œdema, while adding salt again is accompanied by increase of the fluids retained (Javal and Widal). A similar phenomenon is observed when sodium bicarbonate is given in large doses in diabetes. While such cases are very striking we can hardly suppose that salt is the only sinning material, but may regard it as an electrolyte whose accumulation in the tissues is accompanied by fluid as a natural result of the osmotic pressure of the salt. Maries regards the tissues as the element holding the salt, either in a free condition when fluid is attracted or combined with the protoplasm as fixed salt, a hypothesis which would account for the observations of salt retention without œdema. The fact that the chlorides are reported to be present in greater quantity in œdema fluid than in blood serum is perhaps in favour of Maries' view that the tissues attract and hold the salt, but whether this be so or whether the kidney cannot excrete it, it is important to know what indications for treatment have been afforded by the workers in this field.

It has been shown that in cases of retention if the salt in the food be diminished the body soon comes into salt equilibrium.[47] About from two to six grammes a day may be allowed. There need be no fear of doing harm, for a normal individual can subsist on this amount without losing more than the intake in the urine. With this small quantity of salt the œdema and the general condition of the patient improve. Since salt in the tissues attracts water by withdrawing it from the food we are practically giving the patient water. We may also conclude that in ordinary cases of granular kidney which are doing well there is no need to reduce the salt below a moderate amount, but that this should be done when any signs of an exacerbation present themselves.

In conclusion, Mr. President and Fellows, I may express the hope that further research upon the processes of nutrition in disease may be ardently prosecuted in this country. Only by fuller knowledge can the art of healing be advanced. It is important to remember that the information acquired by means of experimental investigations must be combined with the wisdom of clinical experience and that the means employed for the relief of illness must be adapted to the bodily state and to the circumstances of the individual. I cannot do better in this connexion than read to you the words of Bacon: "Physicians are some of them so pleasing and conformable to the humour of the patient, as they press not the true cure of the disease; and some other are so regular in proceeding according to art for the disease, as they respect not sufficiently the condition of the patient. Take one of a middle temper; or if it may not be found in one man, combine two of either sort ...."

insipidus may be regarded as the result of a persistent vaso-dilatation, implicating specially the renal vascular area. If this area alone, as is usually the case, is affected no sugar is found in the urine, but it sometimes happens that a mixed condition of diabetes insipidus and mellitus exists—in other words, that an excessive amount of urine of low specific gravity is passed containing a limited amount of sugar. In these cases I consider the vaso-dilatation is not restricted to the kidney, but also implicates, to a greater or less extent, the vessels of the chylopoietic viscera. My experience has supplied me with an instance where the patient for a time was the subject of well-marked diabetes mellitus which subsequently completely disappeared, and was some time later followed by pronounced diabetes insipidus. It is common in diabetes insipidus, as in diabetes mellitus, to meet with an associated neurotic disposition. Exophthalmic goitre, in my opinion, may be referred to as affording an instance of a disease connected with a local vaso-dilatation. After the disease is established the altered secretion of the thyroid may produce ill effects upon the system; but primarily, it seems to me, a vaso-dilatation of a particular area constitutes the condition to be dealt with. It is well known that this disease is associated with the neurotic disposition, and I believe it to be essentially a neurosis affecting a particular part of the vaso-motor system. It sets in from mental shock, &c., like other neurotic diseases, and subsequently pursues the same kind of course. Not infrequently more or less glycosuria is present. In these circumstances I should consider that the vaso-motor abnormality involves to a greater or less extent the vessels belonging to the chylopoietic viscera.

Grosvenor street, W.

ON THE

ACTION OF VENOMS OF DIFFERENT SPECIES OF POISONOUS SNAKES ON THE NERVOUS SYSTEM.

BY GEORGE LAMB, M.D. GLASG.,
CAPTAIN, I.M.S., DIRECTOR, PASTEUR INSTITUTE OF INDIA,
AND
WALTER K. HUNTER M.D., D.SC. GLASG., F.F.P.S. GLASG.,
PHYSICIAN, GLASGOW ROYAL INFIRMARY, LECTURER IN PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW

V.—VENOM OF COMMON KRAIT (BUNGARUS CŒRULEUS).

IN continuation of our previous papers on the above subject[1] we have now to take up a fourth venom—namely, that of the common krait (bungarus cœruleus). This snake, one of the common poisonous snakes of India, is of small size. Its venom is, however, of much greater toxicity than that of the cobra—in fact, than that of any other terrestrial Indian species. When tested subcutaneously on rabbits it is found that the minimum lethal dose of bungarus cœruleus venom is at least a third that of cobra poison. This much greater toxicity of the poison compensates for the small amount which on account of the small size of the snake is injected at each bite. There can be no doubt that this snake is responsible for a great number of the fatalities from snake-bite, especially in the northern portion of India, where the species abounds. The venom is extremely difficult to procure, as even experienced snake-catchers handle this agile reptile with a considerable amount of reluctance. It is for this reason, and for this reason only, that the amount of work which has been done on the physiological action of bungarus cœruleus poison is very small. In fact, we can find in the literature mention of the subject only in two papers—one by Rogers,[2] and the other by Elliot, Sillar, and Carmichael,[3] working in Sir T. R. Fraser's laboratory.

While Rogers came to the conclusion that the symptoms following poisoning by this venom are identical with those following poisoning by cobra venom, the results got by the last-mentioned workers "seem to indicate that while these symptoms are similar, still they differ so much in relative degree as to render it doubtful if they can in future be spoken of as identical." No particulars, however, so far as symptoms are concerned, are given by these observers as to how this relative difference is to be determined. Our experience after many experiments on monkeys and rabbits has convinced us that even a trained observer without physiological instruments could not tell the difference between the symptoms of cobra venom intoxication and those seen in cases of poisoning with the venom of the common krait. Differences in physiological actions are to be observed but these differences are not, in our opinion, apparent in the symptoms which are observed after the injection of the poisons. It is therefore unnecessary for us again to detail these symptoms, an account of which has already been given in connexion with cobra venom in our first communication. We need only mention that paralysis, beginning in the skeletal muscles and gradually involving the muscles of respiration, is the most prominent symptom, and the symptom which dwarfs those that might arise from any action which the poison might have on the circulatory apparatus. From observations of the symptoms alone one would at once conclude that death in krait poisoning was due to failure of the respiratory mechanism.

If the poison is injected intravenously in sufficient amount very rapid death takes place but no intravascular thrombosis can be demonstrated. Further, in the more chronic cases there is no diminution of the blood coagulability. We have also been unable to show any action of the venom whatever *in vitro* on citrate or oxalate blood plasma. As one of us[4] has already dealt with the action of this venom on the red blood corpuscles we need not further enter into that question. As regards its action on the heart and circulatory apparatus some interesting observations have been made by Elliot, Sillar, and Carmichael. They show that this venom has a decided action on the circulatory apparatus in general, which action is to a certain extent similar to that of cobra venom. It may be said to be similar to cobra venom in its action on the heart muscle or its nerve end mechanism, in its cardio-inhibitory action, and in its direct action on the arterial muscle or its nerve end mechanism. These actions are, however, much more feeble than the corresponding actions of cobra venom. In addition to these effects krait venom has another and important action on the circulatory apparatus which is wanting in the case of cobra poison. An injection of the poison is followed by a well-marked fall of blood pressure, which fall is due to a dilatation of the smaller arteries throughout the body and is probably of central origin—in other words, a paralysis of the vaso-motor centre.

With this brief introduction, which really embodies all that is known about the physiological action of bungarus cœruleus venom, we may now pass on to detail the observations which we have made with a view of ascertaining if any histological changes could be demonstrated in the nervous system of animals intoxicated with this venom. We have examined the nervous systems of four monkeys dead at different intervals after the injection of the poison and also the central nervous system of a man who died a few hours after being bitten by a krait. The following are the details of the monkeys.

Animal.		Weight in grammes	Dose of venom in milligrammes per kilogramme.	Time before death.
Monkey No	31	2730	0·01	16½ hours.
,,	32	2620	0·025	12 ,,
,,	33	2590	0·05	10 ,,
,,	34	2560	0·08	4½ ,,

The tissues from the first three, Nos. 31, 32, and 33, were fixed in perchloride of mercury; those from No. 34 in formol. Sections from all were stained (1) with thionin according to Nissl's method, and (2) with hæmatoxylin and eosin. Portions of the central and peripheral nervous systems in all of them were also fixed and stained according to Busch's method.

Monkey No. 31, weight 2730 grammes, died in 16½ hours what gives rise to these wrong chemical procedures, resulting in the abnormal presence of sugar. The association of the pancreas with diabetes I have already dealt with, and have suggested that it may be explained by the proper enzyme influence for determining normal metabolism in relation to carbohydrate being missing as a result of the absence of the internal secretion of the organ. Here, the pathogeny of the condition, under the view enunciated, has a foundation of a simple and direct nature. Little or no doubt, I consider, can be entertained that the nervous system plays an important part in connexion with the pathogeny of diabetes. The production of glycosuria in Bernard's celebrated puncture of the medulla oblongata experiment affords a conclusive illustration of nerve connexion with glycosuria and the vaso-motor system of nerves may reasonably be considered to constitute the medium through which the effect is produced. It has been observed that vaso-motor paralysis, implicating the vessels of the chylopoietic viscera, follows the *piqûre* operation. Lesions of certain parts of the sympathetic system of the neck, as I many years ago pointed out, produce, like *piqûre*, glycosuria. They also lead to the same kind of vaso-dilatation. Obviously with this paralytic vaso-motor condition the circumstances as regards the blood in relation to the liver must be materially altered. The volume of blood and rate of transit must be much increased and, at the same time, its character must be modified. Observation upon the ear of a rabbit, where the cervical sympathetic has been divided, tells us that the blood passes through the capillaries in such volume and with such velocity as to escape being brought into the ordinary venous condition. The veins are seen to be filled with semi-arterial instead of proper venous blood. In these circumstances, vaso-motor paralysis of the chylopoietic area must have the effect of placing the blood in the portal vein in a semi-arterial condition and experiment has shown that the passage of blood of this nature through the liver leads to the production of glycosuria. Apparently the altered state of blood affects the surroundings of the glycogen in such a manner as to lead to its abnormal transformation into sugar. The increased velocity of the blood arising from the vaso-motor paralysis may further contribute to disturbing the natural course of action, alike at the seat of absorption and in the liver. Thus, purely through an altered state of the blood-vessels, induced by an influence emanating from the nervous system, the source of production of the sugar abnormality belonging to diabetes may arise. Support is given to the view that has been submitted by the information supplied through the medium of the vascular condition of the tongue in connexion with diabetes. In many cases of diabetes nothing special is observable in relation to this point. In others, however, a strikingly red appearance is presented. The surface is clean and of a more or less bright red colour, giving a resemblance to a piece of raw meat. The organ is in a hyperæmic state, for the production of which it is evident that local arterial dilatation must exist. This may be regarded as the specially characteristic tongue of diabetes and the condition is not of unfrequent occurrence. The point of importance connected with it is that its most highly marked form is associated with the worst cases of diabetes. Ordinarily speaking, it may be taken as an indication of severity of disease. In the worst and most acute case of diabetes that I think has ever fallen under my observation not only the tongue but the whole of the interior of the mouth was in an intensely hyperæmic condition. A fact of much interest remains to be,mentioned. It is, that as improvement under treatment occurs in the diabetic state a more or less marked reduction of the redness of the tongue is, as a rule, found to occur.

---

I have spoken of vaso-motor paralysis implicating the chylopoietic viscera as probably constituting one source, if not the main source, of diabetes. The tongue belongs to a portion of the alimentary tract and thus may be looked upon as being connected with the chylopoietic system. Holding this position, it seems to me that what is clinically observable in connexion with the tongue may be regarded as having a reconcilable footing. The question resolves itself into extent of area of vascular implication. The tongue may or may not be involved, according to the particular circumstances existing, and it is not surprising that it should be involved in cases of the highest intensity. For many years my attention has been fixed upon the point to which I have been alluding, and I feel satisfied that the particular character of the tongue referred to has a direct bearing in connexion with diabetes. I do not state that the tongue is necessarily involved in all severe cases, nor do I state that the case is necessarily severe because the tongue is seen to be hyperæmic. I conceive that through the incidental circumstances belonging to the case the vessels of the tongue may or may not fall within the area of vaso-motor paralysis. I need scarcely say that the hyperæmic state may be found apart from diabetes, and with reference to these cases I can state that in more than one instance I have noticed sugar occasionally present to a slight extent in the urine to which, through the promptings aroused by the state of the tongue, special attention has been given.

A hyper-oxygenated state of the blood can be produced through the medium of respiration and the effect is confirmatory of what has been stated with regard to the production of glycosuria by defective de-arterialised blood. In my writings I have recorded experiments where marked glycosuria was observed as a result of the inhalation of oxygen. It happens, however, with this mode of experimenting that hyper-oxygenation of the blood is not always obtainable on account of the natural tendency of the respiratory movements to adapt themselves to the increased oxygenating efficiency of the agent employed. In other experiments recourse was had to a pumping arrangement, whereby inflation of the chest could be induced at any desired frequency, and thus, even with the employment of air, hyper-oxygenation of the blood could be effected. Here also glycosuria proved to be susceptible of being produced. Hence, simply through an alteration of the condition of the blood in relation to its oxygen, metabolism may be deranged and glycosuria induced. The arteries fall into connexion with the matter through the medium of the governing effect of their muscular coat on the flow of blood through the capillaries and in the train of further connexion the muscular coat of the arteries is under the controlling influence of the nervous system. Thus the nervous system is brought into relation with metabolism through the intervention of the capillary circulation in the particular vascular area concerned.

I think it may be taken to be by general consent admitted that the nervous system is involved in the pathogeny of diabetes. Such an array of evidence from all sides can be adduced as to leave no doubt that cerebral action is intimately related, as an influencing factor, to the disease. It is in connexion with the neuropathic disposition that it is most frequently found to exist and the more sensitive and highly strung the nerve organisation the more intense is the form that the disease assumes. A cerebral influence over the vaso-motor state is what is suggested as constituting the link between brain and diabetes. We know comparatively but little at present of the physiology of the vaso-motor system of nerves through which cerebro-spinal influence upon vessels is exerted. The fact that such influence is in constant operation is sufficiently evident from the incessant vascular changes from mental and emotional states that are taking place. Certain parts of the grey matter of the brain appear to be in touch with blood-vessel areas and it is submitted that the nerve filaments of the sympathetic system are not only connected with the spinal cord and medulla oblongata but with spots at the surface of the brain which stand in the position of cerebral vaso-motor centres. Upon these grounds a chain of connexion becomes established rendering it possible for diabetes to constitute a disease belonging to the neurosis class, the difference in its cas being the implication of a particular area belongin to the vaso-motor system instead of structures connecte with voluntary motion, sensation, and the mind. There i ample evidence of different kinds to show that cerebral state are capable of producing a marked influence upon the condition of the circulation in particular areas and the mor sensitive the person the greater is the susceptibility to th occurrence of the manifestation of the influence. Th flushing of the face from an emotional cause affords a goo illustration of the point in question. The watering of th mouth as a result of a passing thought in connexion wit food supplies another, for an altered vascular state of th salivary glands may be considered to stand at the foundatio of the flow of saliva that takes place. The kidney is a organ which is frequently giving evidence of the influenc of cerebral action upon a particular vascular area. Neuroti polyuria is an effect of common occurrence in associatio with different cerebral conditions. I consider diabete admission to hospital the patient was semi-comatose and complained of difficulty in breathing and later of a burning sensation in his left hand and arm. Breathing became more and more embarrassed and ultimately ceased about 6 A.M. two hours after admission to hospital. A small puncture was found on the inside of the ring finger of the left hand.

The post-mortem examination was made four hours after death. The brain and spinal cord, the only tissues examined, were fixed in formol. The snake was found dead in the morning. It was identified as a bungarus cœruleus. Sections from the cerebral and cerebellar cortices, from the pons, the medulla, and the cord were stained with (1) thionin, (2) hæmatoxylin and eosin, and (3) with Busch's fluid. The cortical cells did not stain well, probably due to a fault of fixing, so that nothing definite can be said in regard to them. But the motor ganglion cells throughout the pons, the medulla, and the cord were practically normal. They stained possibly more intensely than normal and some of them too diffusely, but no fragmentation or disappearance of the Nissl granules was to be seen such as was met with in the motor ganglion cells of the first three monkeys. The cells of the tenth (motor) nucleus were equally normal with those of the seventh and twelfth nuclei. With Busch's stain no degenerate fibres were detected.

We have said that the symptoms produced by the venom of bungarus cœruleus are about identical with those on injecting cobra venom, and we may now add that the histological changes in the nervous system in the former intoxication are in general similar to those that we have already described as characteristic of the latter. With bungarus cœruleus venom, however, the chromatolysis seemed less acute, for after ten hours, as in monkey No. 33, though the signs of degeneration were undoubted, they were not so far advanced as with cobra venom after six hours. There were not so much vacuolation and breaking up of the cell generally. In monkey No. 34, too, the appearances were practically normal, showing that with bungarus cœruleus venom more than four and a half hours must elapse before definite signs of degeneration show themselves. We have already noted that the chromatolytic process in the individual cells seemed less acute than with cobra venom, for there was evidence in certain cells of a definite fragmentation of the Nissl granules and of the process being, to begin with, perinuclear and extending thence towards the periphery. This venom, like cobra venom, seems widespread in its action. But in comparing the ganglion cells at various levels of the central nervous system in these four monkeys it seemed as if it was also somewhat selective. In the cord the degenerative process seemed more advanced in the dorsal than in either the cervical or lumbo-sacral regions. And taken as a whole the cells of the anterior horns of the cord were more affected than those of the cranial nuclei (excepting the nucleus ambiguus). The process was uniformly most advanced in the cells of the reticular formation, excluding the nucleus lateralis, which nucleus seemed little more affected than the twelfth nucleus. The cells of the cortex were about equally affected with those of the bulbar nuclei. But while in a measure selective, this bungarus cœruleus venom is too widespread in its action to draw any definite conclusions from the histological examination in regard to any special action it may have on the centres in the medulla. All we can say is, that the more mesial cells of the reticular formation, which probably contain the respiratory centre, are most affected; and that the lateral nucleus cells, in which, we take it, lies the vaso-motor centre, are much less affected—not much more than the twelfth nucleus, which in turn is less affected than almost any other motor ganglion cells throughout the whole nervous system. This venom would also seem to have a widespread action on nerve fibres as well as on ganglion cells. Monkey No. 32 shows this well, for in this animal the intra medullary fibres as well as those in the peripheral nerves were examined by means of Donaggio's stain. There was no definite breaking up of myelin or axis-cylinders but the outline of both was in many places altered and both retained the stain much more tenaciously than do normal fibres. The staining was not so intense, however, as with cobra venom, for with this poison the axis-cylinders stained much more deeply even after a considerably longer period in the decolourising fluid. Indeed, it was with difficulty that one could decolourise the axis-cylinders in cobra poisoning. If this intensity of staining is an indication of the extent of the change in the axis-cylinders (and we take it that this is Donaggio's view) then the action of cobra venom on axis-cylinders is much more marked than that of bungarus cœruleus venom.

As to the human case which we have recorded, the examination of the central nervous system was negative. This may be due to death taking place too quickly for histological changes to develop. We have seen that in the monkeys not less than four and a half hours appear to be necessary before changes show themselves. In the human subject the ganglion cells are probably more stable, and this period is therefore probably somewhat longer. We do not know how long the man lived after being bitten, but it was almost certainly not less than three hours and probably from six to eight hours. It is doubtful if sufficient time had elapsed for degenerative changes to show themselves in the ganglion cells.

22 FATALITIES WHICH HAVE OCCURRED UNDER ETHYL CHLORIDE.

BY THOMAS D. LUKE, M.B. R.U.I., F.R.C.S. EDIN.,
LECTURER ON ANÆSTHETICS TO THE UNIVERSITY OF EDINBURGH.

SOME three years have elapsed since ethyl chloride came into general use in this country and it recently occurred to me that it would be both interesting and profitable to collect as far as possible all the fatal cases which have occurred up the present time. Naturally this has been no easy matter, but up to the time of writing it has been possible to collect 22 fatal cases, in regard to some of which very complete details are available.[1] It cannot be supposed that the list is in any way a complete one, for there is perhaps a not unnatural reluctance on the part of every medical man to shrink from the publication of any cases in which he has been unfortunate or has made an error in judgment; and though a death from an anæsthetic is by no means necessarily due to want of skill on the part of the administrator, still there is a widespread impression that the less there is said about such unhappy events the better for all concerned.

At the present moment it might be said with some truth that all the profession (and I include the sister profession of dental surgery), like ancient Gaul, is divided into three parts. We may roughly divide it into (1) those members who use ethyl chloride with some discrimination and intelligence and deprecate its routine employment in the place of the very much safer nitrous oxide; (2) those who employ ethyl chloride with more enthusiasm than discretion; and (3) those who do not use it at all but, with a conservatism more remarkable than to be admired, faithfully adhere to chloroform when any anæsthesia, however brief, is indicated. It is to be hoped that the publication of the following series of fatalities may confirm the first class in their position but make it plain at the same time to the second that ethyl chloride is not a substance to recommend offhand to anyone who comes into the surgery, but requires for its safe administration discrimination, caution, and skill.

CASE 1. *Lotheissen's case* (at Innsbruck).—The patient was a very strongly built man with an alcoholic history. After the narcosis had been maintained for about three minutes he became very cyanosed. Some fresh ethyl chloride had just been added as there was a tendency to struggle on his part. The corneal reflex had disappeared and the respiratory muscles were in a state of spasm; the patient's face was markedly cyanosed, and the pulse could not be counted at the wrist. Finally the heart ceased to beat altogether. It was estimated that five cubic centimetres of ethyl chloride had been inhaled. The form of inhaler employed was the semi-open mask of Breuer. At the necropsy some eccentric hypertrophy of the heart was noticed with fatty degeneration, the coronary arteries were in an atheromatous condition, and the blood was cherry-coloured, as seen in cases of carbon monoxide poisoning.

CASE 2. *Bossart's case.*—The patient, a child, aged 12 months, required a tracheotomy for the relief of stenosis of the air passages caused by diphtheria. Three cubic centimetres of ethyl chloride were administered; the after subcutaneous injection of 0·01 milligramme per kilogramme of bungarus cœruleus venom. In the anterior horns of the cord not a normal ganglion cell was to be seen, though various stages of the degenerative process were represented. The majority of the cells were skeletons, quite well stained, but with no granulation whatever; some were vacuolated. The more central and internal cells seemed most affected and many of these were mere shadows (ghost cells). In the cervical and lumbo-sacral enlargements some three or four cells were to be seen in the lateral groups of each horn rather too diffusely stained and with the remains of Nissl granules still present. These granules were mostly confined to the periphery of the cell, the perinuclear area being most often devoid of granulation. In most of the cells the nucleus was central, but in many of them it was diffusely stained and this we take to be "homogeneous degeneration" of the nucleus. The degenerative process generally seemed rather less marked in the cervical and lumbo-sacral enlargements than in the upper cervical and dorsal regions of the cord. And comparing the appearances with those of cobra venom poisoning there is the suggestion that here we have a less acute degenerative process going on. With cobra venom the degeneration seemed to affect the whole of the Nissl granules in the cell at the same time, the granules seeming to disappear as if they were being dissolved out. Here, however, with bungarus cœruleus venom certain of the cells suggest that the degenerative process is to begin with perinuclear, extending thence towards the periphery of the cell. In the medulla and pons changes were to be found similar to those in the cord and not one normal cell could be found. In the twelfth nucleus most of the ganglion cells were deeply and some rather diffusely stained. Some again had the remains of their Nissl granules still present; the remaining cells were skeletons, quite devoid of granulation. In the lateral nucleus the changes were similar to those in the twelfth nucleus. But the remaining cells of the reticular formation were much paler, many of them mere "ghosts," and suggested a still more advanced stage of degeneration. The cells in the seventh, sixth, fifth (motor), and third nuclei were similar in appearance to those of the twelfth nucleus. In the ganglion cells of the cortex the changes were similar to those described in the cord. In some cells there were fragmented granules at the peripheral with a homogeneous perinuclear area and in others very definite vacuolation. There were also undoubted degenerative changes in the ganglion cells of the cerebellum. With Busch's stain there was no appearance of degenerative fibres in the cerebrum, cerebellum, or cord.

---

[1] Since then a further fatality has, I believe, occurred at Guy's Hospital.

Monkey No. 32, weight 2620 grammes, died in 12 hours after subcutaneous injection of 0·025 milligramme per kilogramme of bungarus cœruleus venom. In this animal the microscopic appearances were very similar to those of monkey No. 31. In the cord there was possibly a slightly larger proportion of cells with diffuse staining of the plasma and in the lateral groups of the anterior horns in the cervical and lumbo-sacral enlargements a few cells were to be seen with their Nissl bodies still present and but little fragmented. In other cells vacuolation was very evident. But the majority of the ganglion cells in the anterior horns were best described as deeply stained skeletons quite devoid of granulation. In the medulla the more internal groups of ganglion cells of the reticular formation were here also almost all ghost-like and much broken up. But in marked contrast were the cells of the twelfth nucleus which were deeply and rather diffusely stained and many of them with some granulation still present. In the cells of the lateral nucleus the degeneration was more marked than in the twelfth nucleus but much less so than in the other cells of the reticular formation. The appearances in the seventh, sixth, and third nuclei were like those in the twelfth nucleus. In the cerebral cortex most of the smaller cells were pale and without granulation. The larger cells were much more deeply stained, some diffusely stained, and most of them still contained some granulation, though in many it was limited to the periphery of the cell, the perinuclear area being devoid of granules. In the cerebellum the cells of Purkinje were similar to those in monkey No. 31. They were diffusely and deeply stained, with no proper differentiation of their chromatic granules. With Busch's stain there was no appearance of degeneration in the fibres of the cortex or cord. But on staining the cord (longitudinal as well as transverse sections) according to Donaggio's method, there was no doubt as to the large proportion of fibres that showed signs of an early degeneration. There was but little swelling of the axis-cylinders, though many were tortuous in their course and retained the stain much better than in normal fibres. The myelin in places was ill differentiated from the axis-cylinder, its outline was not well defined, and it also stained more deeply than normal.

Monkey No. 33, weight 2690 grammes, died in ten hours after subcutaneous injection of 0·05 milligramme per kilogramme of bungarus cœruleus venom. In the cord most of the central cells and a proportion of the lateral cells were pale and without granulation. The rest of the cells in the lateral groups were rather deeply and diffusely stained, some with the granules a good deal fragmented but a proportion with their granules still intact. The process seemed most advanced in the dorsal region where cells with vacuolation were to be seen. In this dorsal region some slight capillary hæmorrhages into the grey matter were present. In the medulla the cells of the twelfth nucleus seemed practically normal. Those of the lateral nucleus stained too diffusely and they were somewhat deficient in granules. The other cells of the reticular formation (including the tenth motor) were pale and almost devoid of granulation. The cells of the seventh and third nuclei seemed like those of the twelfth—almost normal. The larger cells of the cortex were but little changed. They were possibly rather deeply stained and their granules were therefore not so sharply defined as they should be, but no definite fragmentation was to be made out. With Busch's stain there was no appearance of degenerate fibres in the cerebrum, cerebellum, or cord.

Monkey No. 34, weight 2560 grammes, died in four and a half hours after subcutaneous injection of 0·08 milligramme per kilogramme of bungarus cœruleus venom. In this animal there were but few signs of the degenerative process seen in the three former cases. In the anterior horns of the cord the more internal cells were pale, with some deficiency in their granulation, but the cells of the lateral groups were practically normal. They possibly stained rather deeply and diffusely but in almost all of them the Nissl granules were consistent and fairly well defined. The appearances in the medulla and cortex were as in the cord. With Busch's stain there was no reaction for degenerate fibres in the cord, cerebrum, or cerebellum.

The peripheral nerves examined in these four monkeys were right and left vagi, right and left medians, and right and left posterior tibials. They were stained by the methods of (1) Busch, (2) Donaggio, (3) with hæmatoxylin, and (4) in monkeys Nos. 32 and 34, with Congo red (for axis-cylinders). The nerve terminals were also examined, having been fixed and stained in osmic acid and teased out in xylol. With Busch's method no unequivocal reaction of degeneration was obtained, but Donaggio's stain showed undoubted signs of an early degeneration. In a large proportion of the fibres the axis-cylinders and myelin were irregular in outline, they seemed to run into each other in places, and they stained much more deeply than normal fibres. With Congo red slight swellings of the axis-cylinders were also to be made out, rather more marked in monkey No. 32 than in No 34. No definite increase in the internodal nuclei could be seen.

As to the nerve terminals, the changes were most marked in monkey No. 31. In this animal very few normal fibres were to be found. In most of the fibres the myelin was broken into segments and instead of running a straight course along the margins of the fibre it had a wavy outline—that is to say, the myelin was still intact (except for its segmentation) but instead of being in straight lines the lines were tortuous. In places in some of the fibres little dots of fragmented myelin were to be seen in the centre of the fibres. Some few fibres stained diffusely, showing no differentiation of the myelin. They looked as if the myelin had passed into solution and overflowed into the region of the axis-cylinder. The appearances of the nerve terminals in the other monkeys were much the same as in monkey No. 31, only the proportion of normal fibres in Nos. 33 and 34 was much greater, being in No. 34 very considerable. The following are the details of the human case.

A soldier found a snake in his bed about 9.30 one night. He picked it up and tossed it to a comrade who was standing near. After playing about with it for some time they apparently killed it by hitting it on the head and thrusting a fork through the head. The original finder of the snake then picked it up and putting it in his shirt got into bed. About 3.30 A.M. his comrades noticing that the man was ill, took him to hospital where he died at 6.10 A.M. On fused by dense adhesions; there was a considerable amount of endocarditis present, both old and recent. The liver, spleen, kidneys, &c., were in a condition of passive congestion.

Case 8.—The patient was a stout, alcoholic woman, aged 50 years. She was suffering from cellulitis of the hand and forearm and it was necessary to remove a ring from her finger as it was cutting deeply into the tissues. Six cubic centimetres of ethyl chloride were administered in a modified Ormsby inhaler, the patient being in the semi-recumbent position. Anæsthesia was quietly induced and the mask was removed. Spasmodic twitching of the head and eyes towards the right was now noticed, passing off quickly on the approach of consciousness. The mask was again applied but no more ethyl chloride was added. A few seconds after its removal for the second time the breathing, which up to then had been easy and unembarrassed, suddenly stopped and the pulse was found to have disappeared. Artificial respiration was persisted in for upwards of half an hour but was unavailing, no cardiac impulse being again detected. At the necropsy (which was performed 48 hours later) a marked pallor was noticeable in all the viscera. The heart was empty, the left ventricle was very thin, and the liver was large and fatty. The stomach was greatly dilated and both kidneys were cirrhotic.

Case 9.—The patient was a woman, 40 years of age, with good general health and somewhat stout in appearance. She had once had a fainting fit and occasionally palpitation. Ethyl chloride, or rather somnoform, was given for the extraction of some 17 teeth. After seven teeth had been extracted the patient's breathing was noticed to be very shallow and then ceased altogether. Immediately restorative measures were applied, including artificial respiration, oxygen, strychnine, and galvanism, but the woman never made any attempt to breathe again, although the pulse did not cease for some time after the breathing had stopped. At the necropsy the heart was found to be "covered with an accumulation of fat."

Case 10.—A boy, aged 14 years, was admitted to the Royal Albert Hospital, Devonport, suffering from an injured finger and while in the hospital he was found to have adenoids. In order that they might be removed he was put under ethyl chloride and a very brief anæsthesia of about half a minute was induced. Just as the patient was regaining consciousness he suddenly turned pale and both pulse and respiration ceased immediately. All restorative measures proved futile. At the inquest death was stated to be due to cardiac syncope.

Case 11.—The patient, a female, aged 50 years, went to a dentist to get two or three teeth extracted. She had previously been warned by her medical man on no account to have an anæsthetic at any time if she could possibly help it, as she had recently had two attacks of pneumonia and her heart was very asthenic. She was put under ethyl chloride by the dentist's assistant, who had a medical qualification, and died in a few moments before any teeth had been removed. At the necropsy no signs as to the actual causation of death were to be noticed but a muscularly asthenic heart.

Case 12.—A man, aged 30 years, was being "put under" with ethyl chloride prior to the administration of chloroform for the removal of a malignant growth. Before the change to chloroform was made, however, the breathing and pulse suddenly ceased and death occurred. At the necropsy extensive malignant growths were found throughout the body.

Case 13.—The patient, aged 20 years, was admitted to a large general hospital for anæmia and bad teeth. There was no evidence of cardiac disease. She was put into a dental chair and anæsthetised by means of five cubic centimetres of ethyl chloride. Five teeth were drawn, when without any change of colour or sign of respiratory obstruction, both pulse and respiration ceased. Artificial respiration was of no avail. The patient had been properly prepared for an anæsthetic. No post-mortem examination was allowed.

Case 14.—The patient was a married women, 50 years of age—"a soaker." There was no evidence of heart disease. She was suffering from a suppurating bursitis in the elbow. An anæsthetic was administered in the out-patient department with the patient in the supine position, three cubic centimetres of ethyl chloride being used. She went under all right but with a good deal of struggling. The mask was removed and the arm was incised; the bursa was scraped out and dressed. Just as the bandage was being applied the patient moved and began to breathe deeply when suddenly the pulse and breathing stopped and she died, all restorative measures being useless. At least one and a half minutes had elapsed since the mask was removed when the breathing stopped. The patient had moved slightly both when the incision was being extended and the bandage was fixed. At the necropsy the right ventricle of the heart was found to be very fatty and at one place no muscle fibre could be seen. The left ventricle was hypertrophied but not dilated; the coronary arteries were patent. There was an old tuberculous patch in both lungs; the liver was in a nutmeg condition and the kidneys were granular.

Case 15.—The patient, a man, aged 67 years, went to a dentist to have three or four teeth extracted. Ethyl chloride was administered to him for this purpose by the brother of the dentist who was a fully qualified medical man. It is said that about five cubic centimetres of the drug were administered; it may be presumed by a close method, but this is not stated. Anæsthesia was induced and three teeth were extracted and the fourth was just being removed when the patient suddenly turned very pale and died almost at once. The ordinary restorative measures were applied but without avail. A necropsy was allowed and carried out by a competent pathologist who found that the heart was in a condition of fatty degeneration. At the inquest the jury returned a verdict in accordance with the medical evidence and no blame was attached to the medical man responsible for the anæsthesia.

Case 16.—The patient was a robust adult male who required to have some teeth extracted. The dentist he consulted gave him the option of nitrous oxide or chloroform but the patient refused both and the dentist finally elected to administer ethyl chloride himself, no assistant being present. Anæsthesia was induced and several teeth were extracted when the patient suddenly made an attempt to vomit and then stopped breathing. The tongue was drawn out and artificial respiration was carried on but without any good result. A tracheotomy was not attempted. At the necropsy no foreign matter causing obstruction of the airway was found in the larynx or trachea. Both lungs and throat, however, were in a state of chronic inflammation. The patient is said to have had "chronic inflammation of his throat for many years," possibly due to the excessive use of tobacco.

Case 17.—The patient, a seaman in the Royal Navy, went to Haslar Hospital to have the stumps of several teeth extracted. He was examined by the surgeon on duty and pronounced fit for the anæsthetic. Ethyl chloride was administered to the establishment of full anæsthesia and the teeth were extracted, the man regained consciousness, but in three minutes he suddenly collapsed and died. All restorative measures were useless. At the necropsy the lungs were found to be congested and the heart empty.

Case 18.—A death occurred recently at a Leeds dispensary.

Case 19.—A death has occurred at Llandudno (dental case).

Case 20.—A death has occurred at Swansea (dental case).

Cases 21 and 22.—Two deaths occurred recently at the Civil Hospital, Mustapha, Algiers.

Remarks and conclusions on the cases.—One is struck by the fact that some of the cases recorded above were very bad subjects for *any* anæsthetic—e g., Nos. 1, 6, 8, 11, and 14. Again, several of them might, with a very much greater degree of safety, have been negotiated with chloroform or a mixture containing it on an open inhaler, rather than with ethyl chloride. For instance, no anæsthetist of experience and sound judgment would have considered it good practice to anæsthetise Cases 2 and 6 with ethyl chloride—in a closed or even semi-closed inhaler at any rate, and the necropsy in Case 5 showed this to be equally unsuitable. Nitrous oxide would have been equally lethal in the circumstances. In Cases 3, 5, 6, and 16 death was obviously due to asphyxia, and in Case 5 at least death could have been avoided by more prompt action. The most unsatisfactory cases from the point of view of the safety of ethyl chloride are 4, 10, and 17. Here we have three patients whose organs were in a healthy condition, who had no alcoholic history and suffered from no constitutional dyscrasia, dying from syncope of just that very sudden and unpreventable character which we have been wont to look for in a certain percentage of chloroform cases. It is noteworthy that *out of these 22 fatal cases no less than eight occurred during dental operations.*

What is the approximate death-rate under ethyl chloride?

operation was commenced, and after about three minutes two cubic centimetres more were added. In spite of the trachea being opened the breathing became worse and worse, the circulation and respiration stopping at last entirely, while the patient became deeply cyanosed and the pupils widely dilated. The mask used was a semi-open one.

CASE 3. *Olcott Allen's case.*—The patient, a coloured man, aged 28 years, was to be operated on for incarcerated hernia. He had been vomiting freely but the vomit was not of a fæcal character, the general condition being good on the whole. Anæsthesia was started by ethyl chloride and progressed satisfactorily until the patient was in full narcosis when a change was made to ether. Just as the ether was applied he vomited and retched, bringing up a large quantity of nearly clear watery fluid. The vomiting ceased in about three or four minutes but the breathing did not begin again, the patient was cyanosed in appearance, and no pulse could be felt. No obstruction could be felt in the throat, but as a necropsy was not allowed this question could not be further gone into.

CASE 4.—The patient, a female, aged 18 years, was suffering from some affection of the sacro-iliac joint, supposed to be either an abscess or sarcoma. She was thin and tuberculous in appearance. After a careful preparation for anæsthesia she was given five cubic centimetres of ethyl chloride by means of an Ormsby inhaler as a preliminary to etherisation. Anæsthesia was easily induced without struggling. At the first sound of stertorous breathing the inhaler was removed and ether was put on the sponge but the anæsthetist noticed before replacing the face-piece that the patient's breathing had suddenly become shallow and on examination it was found that the pulse was not perceptible. Strychnine was injected and artificial respiration was carried out for upwards of half an hour but with no good result. The patient seemed to breathe naturally a few times but the pulse never came back. The pupils were dilated and the reflexes were absent. The amount of ethyl chloride actually inhaled was, in the anæsthetist's opinion, not more than from three and a half to four cubic centimetres. At the necropsy a large sarcomatous tumour arising from the sacral vertebræ was found in the pelvis. There were no secondary deposits and the heart and other organs were quite normal.

CASE 5.—The patient was a robust and healthy man, aged 24 years, who was suffering from a large abscess under the right jaw, alveolar in origin, which was pointing just below the angle of the jaw. He had been unable to take any nourishment practically for three days prior to the operation. His breathing just before the operation was quite normal and there was no dyspnœa or blueness. The heart showed no abnormality of action on examination. Six cubic centimetres of "kélène" (ethyl chloride) were sprayed on to a double layer of lint inserted inside the face-piece of the inhaler and anæsthesia was rapidly induced without any struggling or sign of distress on the patient's part. The abscess cavity was incised (the inhaler having previously been removed) and about two ounces of pus were evacuated. At this moment the patient stopped breathing and the medical man who was looking after the anæsthetic forced open the mouth with some difficulty and pulled out the tongue. Respiration began again, though somewhat imperfectly. The operation was rapidly concluded, when suddenly the breathing again ceased. As artificial respiration seemed ineffectual owing to some throat obstruction tracheotomy was performed, when the air entry became satisfactory but no further respiratory effort was made by the patient in spite of the injection of strychnine and the use of various mechanical stimuli. At the necropsy all the organs were found to be healthy. A large abscess cavity was found, however, extending from the angle of the jaw on the right side to well beyond the middle line of the neck. There was no pus remaining in it. There was very marked œdema of the glottis present but there was a fair amount of passage left for air. On the right side, however, there was a bulging fold of mucous membrane which might have been sucked into the opening and acted as a plug and caused complete obstruction. The medical men concerned were greatly struck by the very marked rigidity present, leading to great difficulty in getting the mouth open; the head and neck were spasmodically fixed in a somewhat retracted position. They concluded that death was due to tracheotomy not being done soon enough to relieve the asphyxial condition which led to secondary heart failure. It was stated that some three minutes elapsed between the arrest of breathing and the establishment of a free airway.

CASE 6.—The patient, a man, aged 67 years, was admitted to a hospital in Birmingham suffering from a swelling of his jaw and neck, accompanied by some dyspnœa. His breath was foul and he had a purulent discharge into the mouth. There was a brawny swelling of the whole lower jaw which had been forming for several months. A diagnosis of malignant growth of the lower jaw was made. The patient was carefully prepared for an anæsthetic and the chest was examined. The heart was found to be enlarged, but the sounds, though feeble, were to be heard distinctly. The expansion of the chest was imperfect, the breath sounds were harsh, the expiration was prolonged, and rhonchi were present. The urine contained some albumin. Six cubic centimetres of ethyl chloride were sprayed into an Ormsby inhaler and anæsthesia was induced without any struggling in about one and a half minutes. At the moment of the incision the breathing was noticed to be shallow and the pupils dilated with a sluggish conjunctival reflex. There was no jaw spasm. The incision having been completed some fluid, chiefly blood, escaped when the patient suddenly stopped breathing. The inhaler, which had been kept on now for about two minutes, was removed, the mouth was wedged open, and the tongue was drawn out. As the patient made no attempt to breathe artificial respiration was at once begun, while the wound was hurriedly stitched up and dressed. The patient began to struggle and tried to get off the table, struggling violently for three or four minutes but not regaining consciousness; at the end of this time the breathing again ceased and he became cyanosed to a marked degree. Artificial respiration was again commenced and carried on for some 15 minutes and strychnine was injected. The pulse could not be felt nor the heart sounds heard. Tracheotomy was performed and artificial respiration was carried out assiduously with rhythmic tongue traction but without any good result and the efforts were finally abandoned. At the necropsy, which was performed by the resident pathologist, a large swelling composed of malignant glands was found in the neck and by means of it the wall of the pharynx was bulged in and pushed almost to the middle line, narrowing its diameter to about one-half the normal. The width of the larynx was also considerably diminished. The laryngeal muscles were invaded by the growth and the left vocal cord was swollen and œdematous. The heart weighed 23 ounces. The heart muscle showed fatty infiltration and the wall of the ventricle was exceedingly thin, in one place being not more than one-tenth of an inch thick. The right ventricle was much dilated and contained blood clot. The liver was in a state of fatty degeneration and infiltration, with recent venous congestion. The kidneys were cirrhotic.

CASE 7.—The patient, a female, aged 29 years, was admitted to a hospital in Dublin suffering from chronic cardiac disease and failure of compensation. Her abdomen was distended with ascites and she was unable to breathe except in the sitting posture. The action of the heart was found to be frequent and irregular. On the day after admission to the hospital the abdomen was tapped and five pints of fluid were withdrawn; she was again tapped on two subsequent occasions and a similar quantity of fluid was removed. It was evident, however, that a large amount of fluid was left on each occasion and the relief afforded was only slight. It again became necessary to tap the patient owing to great respiratory difficulty, and on this occasion, as the patient was exceedingly nervous about the operation, it was decided to give her an anæsthetic so that a larger trocar might be used and greater relief afforded. Owing to the unsatisfactory condition of the breathing and circulation, however, the anæsthetist called in almost refused to give any general anæsthetic, but after some consideration consented and selected ethyl chloride. Between two and a half and three cubic centimetres were administered by means of Luke's inhaler, care being taken to avoid air deprivation. The patient, though obviously very nervous, breathed freely and was anæsthetised in about 15 seconds. The mask was withdrawn and the operation was begun. At this time the patient was breathing well though she was somewhat rigid and cyanosed; a medical man who had his finger on the pulse, however, said that he could not feel it. At the same time the breathing stopped and the patient from that time onwards never made any voluntary effort to breathe. Artificial respiration was zealously carried out for an hour or more, the external jugular was opened, and hot cloths were placed over the præcordia but quite without any effect. At the necropsy the heart and pericardium were completely the mastoid process without any involvement of the middle ear. There are eight centres of ossification in the temporal bone, one for the squamous, two for the styloid process, one for the tympanic ring, and four for the petro-mastoid portion. These centres have nearly coalesced about the fifth month of intra-uterine life, but during the remainder of fœtal life the squamous is easily separable by maceration from the petro-mastoid. During the first few years of life also the petro-mastoid and the masto-squamosal sutures are more vascular than the rest of the bone and separation by maceration is occasionally possible. On the outside of the skull of a newly born infant the masto-squamosal line of suture can easily be detected. It commences at the point of junction of the mastoid, parietal, and squamous bones, and then passes downwards and forwards, making with the posterior root of the zygoma an angle of about 45 degrees, until it reaches a point in a line horizontally with the centre of the outlet of the bony meatus—that is, the apex of the supra-meatal triangle. From that point the line drops vertically downwards to the lower surface of the bone. On the inner surface of the infant skull the line of the petro squamosal suture can be distinctly seen running along the junction of the petrous with the squamous. When a fœtal temporal bone is macerated and the squamous is separated from the petro-mastoid it will be seen that the outer wall of the mastoid antrum is formed by the descending plate of the squamous, and that nearly one-third of the masto-squamosal suture line is above, and posterior to, the mastoid antrum. Thus, the line of the masto-squamosal suture can be divided into two parts: (1) an upper part which is above and behind the antrum; and (2) a lower, most of which runs along the posterior border of the descending plate of the squamous—i.e., along the posterior border of the outer wall of the antrum. The point on which stress is to be laid is this—viz., that if a spot of caries occurs along the line in portion (1) it is possible for a perforation exposing the dura mater of the middle fossa to occur without the mastoid antrum being opened up. Two cases which have been under my care illustrate the importance of this point.

CASE 2.—The patient, a boy, aged six years, was admitted into the Birmingham Children's Hospital on May 27th, 1900, complaining of the presence of a swelling over the right mastoid process. In this position was a soft, fluctuating swelling with the skin just becoming red. The history given was that the patient had never had ear-ache or any discharge from the ear and that the swelling had been forming for the past three to four weeks. The membrana tympani on examination appeared quite normal, there being no bulging, perforation, or visible scar. There was no displacement of the auricle. The patient's temperature was normal and he complained of no pain beyond a little tenderness on pressure over the swelling. On June 1st the swelling was incised and proved to contain pus. In a position corresponding to the extreme upper end of the masto-squamosal line was a patch of carious bone of about the size of a split pea. This was scraped away and a sinus was found to perforate through so as to expose the dura mater of the middle cranial fossa. The remainder of the surface of the mastoid and of the descending plate of the squamous appeared quite healthy and so the antrum was not opened. The wound was packed and healed satisfactorily, there never being at any time a discharge from the auditory meatus.

CASE 3.—The patient, a girl, aged five years, was admitted into the Children's Hospital, Birmingham, on Nov. 13th, 1900, complaining of a swelling over the right mastoid which had been forming for three weeks. There had never been any otorrhœa and there had been no complaints of pain. The membrana tympani appeared to be normal. During the next three days the patient's temperature varied from 98·6° to 99·5° F. There was no displacement of the auricle. On Nov. 16th the abscess was opened. At the upper border of the mastoid, just in the position of the upper end of the line of the masto-squamosal suture, was a small patch of carious bone. This was scraped and was found to penetrate almost, but not quite, through to the dura mater. The remainder of the mastoid process appeared to be perfectly healthy. The wound was packed and rapidly filled up.

Here, then, were two cases of what may be called "quiet mastoid abscess," in which the abscess was clearly due to the formation of a patch of caries, presumably tuberculous, in the exact position of the upper part of the masto-squamosal line; in that part of the line, in other words, which has on its deep surface the dura mater of the middle fossa and which is altogether above and behind the position of the mastoid antrum. Had this patch of caries occurred a little lower down in the course of the masto-squamosal line, then, when perforation of the bone took place, the antrum would have been opened up and it would then have been impossible to say whether the disease began as a tuberculous otitis media, which led to secondary caries of the mastoid process, or as a primary caries of the mastoid process which had perforated through the masto-squamosal line into the antrum. In fact, Cases 2 and 3 appear to give the clue to the morbid anatomy of this class of mastoid abscess.

From a study of these cases it seems justifiable to draw the following conclusions: 1. That in young children a form of mastoid abscess not uncommonly occurs (in 10 out of 61 cases) in which there is no history of otorrhœa and in which the membrana tympani appears to be normal. 2. That in these cases the abscess is of slow and painless formation, the patient's temperature not being raised and the ear not being displaced. 3. That in these cases the abscess is due to primary caries of the mastoid, the patch of caries occurring somewhere along the line of the masto squamosal suture, this being in a young child the softest and most vascular portion of the bone. 4. That if the patch of caries forms in the upper part of the masto-squamosal line and if perforation of the bone occurs the dura mater of the middle cranial fossa is exposed and the mastoid antrum is not opened up. 5. That if the patch of caries occurs in the middle or lower part of the masto-squamosal line the antrum is quickly opened up and then the caries spreads rapidly through the mastoid.

When the patch of caries is found to be situated in the upper part of the masto-squamosal line and the rest of the mastoid is healthy, then it can be taken that the abscess was caused by a primary caries of the mastoid. When, however, the patch of caries is found to be situated in the middle or lower part of the masto squamosal line—i.e., in that part which runs along the posterior boundary of the supra-meatal triangle—it must remain uncertain whether the abscess is due to primary caries of the mastoid or to tuberculous inflammation of the middle-ear. But, reasoning by analogy, it seems at all events probable that mastoid abscesses of this class have a common origin—viz., in caries of the mastoid process; that the patch of caries occurs nearly always along the line of the masto squamosal suture and that whether the mastoid antrum is opened up or not depends upon the exact position in the line of the suture at which the caries occurs.

Birmingham.

OBSCURE CEREBRAL MANIFESTATIONS OF TUBERCULOSIS.

NOTES ON THREE CASES.

BY J. FORTUNE, M.B., CH B. EDIN.,
ASSISTANT MEDICAL OFFICER, DEVON COUNTY ASYLUM.

THERE are few diseases which do not appreciably upset the intricate mechanism of the nervous system, but it is surprising in how few the disturbance is betrayed by prominent symptoms or remains a permanent one. It is not perhaps so surprising to observe in how many different forms the disturbance is manifested. The following notes on two cases in which the cerebral symptoms were the most urgent and in which post mortem lesions of tuberculosis were apparent will serve to show, however, the difficulty of tracing these disorders to their proper source, while Case 3 may serve to accentuate the diversity that occurs. Tuberculosis, even when confined to one organ, may appear in the most divergent forms, and when diffused the unity of the disease may not always be determined. It is similar in its secondary effects on the nervous system. So often has the unreasoning hopefulness accompanied the progress of the lung affection that the "*spes phthisica*" has come to be regarded as characteristic. In phthisical insanity, again, the variableness of mind, the unsocialness, or irritability with suspicion, even at times monomania, have all appeared and been regarded as symptomatic. Indeed, the insanity has been stated to begin usually before any marked symptoms of pulmonary tuberculosis appear,[1] and this may account for

---

[1] Clouston: Mental Diseases.

In 1902 Seitz of Constanz endeavoured, with the material then available, to establish the relative mortality under ethyl chloride, and investigated something like 16 000 cases, chiefly on the continent, and he found that up to that time only one fatality had been recorded (that of Lotheissen) and he accordingly fixed the death rate at 1 in 16,000. I may endeavour at the present time to make a rough estimate of the mortality as follows. There are some 35,000 medical and dental practitioners in the United Kingdom at the present moment. One may safely assume that during the past three years at least one-seventh, or 5000, of these have been using ethyl chloride pretty constantly, probably not less often than once in every ten working days—that is to say, that each of them has given ethyl chloride about 30 times per annum on the average, which will amount to 150,000 administrations per annum for the whole profession, or 450,000 for the three years. I find that out of the above list of fatalities 17 occurred in the United Kingdom, so that with these data the mortality works out at 1 in 36,000 approximately, upon which basis ethyl chloride compares very favourably with ether and chloroform. It is almost certain, however, that there have been considerably more than these 22 deaths which have come to light, but even if I were to find on continued inquiry that there were as many as three times the number (and this is rather unlikely) I should still only have a death-rate of 1 in 8000, and the fact remains that ethyl chloride is a *comparatively* safe anæsthetic agent, certainly much safer than chloroform for short operations.

If we except the extraction of teeth, there is probably no operation for which ethyl chloride has been more frequently employed than that for the removal of adenoid growths of the naso-pharynx. In the throat department of the Royal Infirmary, Edinburgh, alone it has been administered on upwards of 1500 occasions without a mishap. And out of the fatal cases above recorded we have only one occurring when the anæsthetic was given for this particular operation. In this case the administrator was a student who had practically no experience of anæsthetics and the operator was a house surgeon who had performed this operation only on half a dozen previous occasions. On examination of chloroform statistics we find that the number of fatalities which have occurred under this drug when used for adenoid operations is very great, and during the decade 1890–1900 no less than 100 such deaths occurred (Chaldecott). This is surely a strong argument for the employment of ethyl chloride and the avoidance of chloroform in operations for the removal of adenoids and tonsils.

As regards *personal experience* I have now administered ethyl chloride to all classes of patients on considerably over 2000 occasions and have been happy in not seeing a single fatality, and indeed nothing worse than two cases of temporary respiratory arrest with considerable cyanosis and very widely dilated pupils. One of these cases was sufficiently alarming and demanded immediate and careful treatment, and such cases, quite apart from actual deaths, make it quite plain that no one should undertake the administration of ethyl chloride at any time unless he is prepared and quite qualified to deal with an anæsthetic emergency. The dangerous symptoms come on with a rapidity not exceeded by the onset of troubles in chloroform anæsthesia. Ethyl chloride is most essentially not an anæsthetic to be administered, as it has been in the past, haphazard, according to the "instructions for use" provided with a new inhaler by the enterprising instrument maker or druggist. In dental work it is best not to give ethyl chloride *alone* but either to give it in mixture with nitrous oxide for short cases, in small doses of from two and a half to four cubic centimetres, or in sequence with ether for the longer cases.

In my opinion the "boom" in ethyl chloride is well-nigh at an end, but while the publication of such a list of deaths as is recorded above may well discourage the promiscuous and irresponsible use of a highly toxic and very rapidly acting anæsthetic, yet one would hope that ethyl chloride will not be unduly discredited or sink into comparative desuetude; it should rather take its proper place as a valuable addition to the anæsthetist's armamentarium for properly selected and suitable cases. The fact, however, that any unregistered dentist, any L.D.S. diplomate, can administer such a drug without let or hindrance under the impression that it is a sort of "glorified nitrous oxide" to any or all of his confiding patients constitutes a public danger which cannot be ignored.

Edinburgh.

ON PRIMARY CARIES OF THE MASTOID PROCESS AS A CAUSE OF MASTOID ABSCESS IN YOUNG CHILDREN.

BY LEONARD P. GAMGEE, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM;
SURGEON TO THE CHILDREN'S HOSPITAL, BIRMINGHAM.

IN young children a form of mastoid abscess not uncommonly occurs without the pre-existence of any discharge from the external auditory meatus and without the presence of any perforation of, or scar on, the membrana tympani. Such was the character of the abscess in ten out of 61 cases of mastoid abscess in children under 15 years of age operated upon by me. These ten cases had the following characteristics in common:—1. In each case the patient was an infant or quite a young child, the youngest being six months old and the eldest seven years. 2. There was no history of otorrhœa, nor did any discharge from the auditory meatus appear during the course of the case. 3. There was no perforation of the membrana tympani visible. 4. The abscess formed slowly, in some cases a month elapsing between the first appearance of the swelling and the first attendance of the patient at hospital. 5 There was a marked absence of pain. 6. The auricle was not displaced downwards and outwards as in the ordinary form of mastoid abscess resulting from suppurative otitis media. 7. There was no elevation of temperature. 8. There was very extensive destruction of bone; but, in spite of this, there were no symptoms of intracranial complications. As an example the following case may be quoted.

CASE 1.—The patient, a boy, aged one year and nine months, was first seen on Dec. 16th, 1898. There was present over the right mastoid process a fluctuating swelling, which had been gradually forming for three weeks. The mother stated that the child had apparently not been in pain and that there had never at any time of his life been any discharge from the external auditory meatus. When admitted into hospital the patient had a normal temperature, the ear was not displaced, and there was no bulging or perforation of the membrana tympani. The child looked in good health and there were no symptoms of any intracranial complications. The abscess was opened and a patch of carious bone was seen on the mastoid process, its exact situation being a point just behind the supra-meatal triangle, in other words, about the centre of the line of the masto-squamosal suture. The carious bone was scraped away and the sinus so formed was found to lead into the interior of the mastoid. It was found that the outer shell only of the mastoid was intact, the rest of the process being carious and in its centre was a sequestrum half an inch square, evidently the result of caries necrotica. The outer shell of the mastoid was cut away and the carious bone in its interior was scraped away, the resulting cavity being three-quarters of an inch deep, the caries having extended into the petrous bone. The wound healed soundly. The patient was last seen 11 months after the operation. The membrana tympani was then unperforated and there had been no otorrhœa.

This was the only case among the ten in which there was an actual sequestrum, but in all the amount of bone destruction was great, in several the sinus groove being opened and the dura mater over the upper surface of the petrous bone exposed. The explanation usually given of the occurrence of this kind of mastoid abscess is that there has been, in the first instance, tuberculous disease of the middle ear and that the disease has spread to the antrum, so causing the mastoid abscess, the membrana tympani remaining intact all the time. But, bearing in mind the mode of ossification of the temporal bone and studying the details of the two cases given below, it becomes manifest that the variety of mastoid abscess under discussion may be due to primary caries of of the objections that occur to classifying them as manifestations of the same disorder. They have only one feature in common—that tuberculous lesions existed and were found post mortem. In Case 2 only were those exhibited in the brain and there the symptoms in reference to it were physical rather than psychical. Phthisical insanity is a distinct disease and embraces none of these cases, which in relation to mental symptoms were classified as melancholia, epileptic insanity, and delirious mania respectively. But it is easy to push the *post hoc, ergo propter hoc*, too far, and it is a known fact that more insane than sane patients die from tuberculosis. Nevertheless, Case 3 had pulmonary tuberculosis before he became insane; Case 2 had tuberculous lesions before he developed the epilepsy which brought the mental symptoms in its train; and Case 1 very probably had Addison's disease while in a state of sanity. They are all illustrative of the benefit derived from post-mortem examination, even where the diagnosis seems perfectly clear. Without such procedure Cases 1 and 2 would have been put down as examples of acute pneumonic phthisis and of ordinary major epilepsy. They each present interesting and debatable features and apart from their suggestiveness they seem, from their intrinsic interest alone, worthy of record.

Exminster.

A SUCCESSFUL CASE OF EPIPLOPEXY FOR CIRRHOSIS OF THE LIVER WITH ASCITES.

BY T. K. MONRO, M.A., M.D. GLASG., F.F.P.S. GLASG.,
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY AND PROFESSOR OF MEDICINE AT ST. MUNGO'S COLLEGE;

AND

A. N. McGREGOR, M.D. GLASG., F.F.P.S. GLASG.,
ASSISTANT SURGEON AT THE GLASGOW ROYAL INFIRMARY.

AT the present time, when surgical procedures for the relief of some of the symptoms of hepatic cirrhosis are being so much discussed, the following case is interesting and its publication may be of value as an item among the many observations necessary to a thorough appreciation of the value of such operations, their scope, and their limitations.

The patient, a man, aged 40 years, was successfully treated by Dr. F. V. Adams in the later months of 1904 for nasal obstruction resulting from enlargement of the turbinates. One day in January, 1905, while feeling perfectly well and walking in the street, he was seized with sickness and vomited blood, after which he fainted for a second or so and fell on his knees. He went home to bed and by the next day seemed all right again and was able to go out. After this he remained to all appearance perfectly healthy until July 10th, 1905, when he was on holiday in Ireland. After a cup of tea at breakfast that morning he felt sick, vomited blood, and fainted slightly, exactly as on the previous occasion. He was kept in bed for a week this time and was fed by the rectum. He has had no other attack of this kind and he can suggest no cause for either of the two attacks. His previous health had always been excellent, apart from slight bilious attacks which he attributed to confinement and want of exercise. He had no cough. He could take any kind of food, his bowels were regular, and he did *not* suffer from piles. He lost about 10 pounds in weight during the week of rectal feeding but appeared to regain this afterwards. According to his own statement, which is corroborated by his friends, he was always moderate in the use of alcohol. About a bottle of beer at supper was the extent of his indulgence. He never took beer in the day-time and he took no spirits at any time. After the first hæmorrhage, which has been described, the stools were black for a time but there were no stomach symptoms. After the second attack the stools were again black for a time, but, in addition, he began to suffer from abdominal pain when he had been in bed for a few days; and, after a few more days, when he began to take food by the mouth he became troubled with distension. The pain, though constantly present, was never very severe but on the whole it tended to get worse as time went on. It did not seem to be related to the taking of food but it was aggravated by pressure and kept him from lying on either side. At the same time his general health remained good.

When the patient was seen on July 27th it was noted that the abdomen was greatly distended. The signs pointed to ascites with flatulent distension of the stomach. There was tenderness at the right lower costal margin, just to the right of the xiphoid, but nothing abnormal was palpated there. The liver could not be felt. Examination of the rectum gave negative results. The lymph glands in the right axilla were somewhat large but those in the other accessible parts were normal. The heart and the urine were normal. Some crackles were heard at the posterior bases but otherwise the lungs were normal. On August 4th, in St. Elizabeth's Nursing Home, the abdomen was tapped and after the ascitic fluid was evacuated the stomach was distended with carbon dioxide, with the result that no great dilatation was found. There was still tenderness in the right hypochondrium.

Operation.—On the 8th the abdomen was opened in the middle line above the umbilicus; a quantity of ascitic fluid was evacuated and there was found cirrhosis of the liver and also an adhesion of the pyloric end of the stomach to the under surface of the liver. No tumour was found in the liver, portal fissure, pancreas, hepatic or splenic flexure of the colon, or pylorus. The stomach was healthy except for some dilatation of the veins. The omentum was then spread out and sutured by means of a fine, continuous, catgut suture to the peritoneal surface of the anterior abdominal wall, first on one side of the incision and then on the other side. There were three rows of sutures on each side. In closing the abdominal wall the first layer of sutures was passed through the transversalis fascia and peritoneum and the omentum was picked up with the needle as it passed from one side of the wound to the other, so that the omentum was attached by seven rows of suture. The rest of the abdominal wound was closed in two layers. The after-history of the patient was uneventful, the wound being healed when it was dressed a week after the operation. He went home on the 23rd—the fifteenth day—and a week later he was allowed to go to the coast for change of air. After a month's holiday he resumed work and he has continued at his occupation without interruption until the present time.

At this date,[1] eight months after the operation, inspection of the abdomen shows a dilated vein, the superficial epigastric, extending from near the umbilical end of the cicatrix to the left groin. No other venous dilatations are observed and the abdominal wall is otherwise normal. No ascitic fluid can be detected in the abdomen and no abnormalities are observed on palpation or percussion.

One of us (T. K. M.) examined the patient on April 2nd and made the following note of his condition: "Mr. —— called this afternoon and expressed himself as perfectly well, being indeed brighter and altogether better than he has been for the last 15 years. He has been a total abstainer since he was in St. Elizabeth's Home. The only symptom he has had since the operation was melæna. This happened once, about two months ago, and if he had not noticed the stools black he would not have known that anything had happened. He attributed it to running for a train or to a twist when he was scrubbing himself in the bath. The liver is reduced in size and there is no tenderness in the right hypochondrium. The spleen is sufficiently enlarged to be easily felt on inspiration. The heart is normal. I note the enlarged superficial epigastric vein running down to the left groin from the scar, near its lower end. There is a good current of blood in it flowing downwards."

The case is one of cirrhosis of the liver characterised by well-marked ascites, by hæmatemesis, and latterly by tenderness of the right hypochondrium, as well as by pain in that region. The condition of the liver was demonstrated by inspection. There are an absence of any serious alcoholic history and no suspicion of syphilis or of malarial or other toxic infection, and there are no tumours in the neighbourhood of the liver, spleen, pancreas, or colon. The operation was simply that of suture of the omentum to the anterior parietes, without rubbing or scraping of the surface of the liver, of the spleen, or of the parietal peritoneum; and, after a lapse of eight months, and with the solitary exception of a trivial hæmorrhage, evidenced only by melæna, the patient reported himself as quite well, and there is satisfactory evidence of a local increase in the venous circulation of the abdominal wall originating at the site of operation.

---

[1] The patient was shown at a meeting of the Glasgow Medico-Chirurgical Society on April 6th, 1906.

the assertion that it has not been shown that more than an average number of phthisical patients become insane (Hector Mackenzie) and may be very suggestive in the consideration of Case 1. Thus much for the lungs.

Disease of the adrenal glands is usually accompanied by nervous symptoms, the chief mental ones being apathy and depression,[2] but the mind remains clear unless coma or delirium supervenes.[3] Other symptoms, such as prostration after exertion and disinclination for exercise, may be common to pulmonary tuberculosis and Addison's disease, where both exist in the same individual. In the following case the existence of suprarenal disease was undetected during the life of the patient, the severity of the symptoms of the lung affection completely overshadowing any sign which might have suggested an additional focus of disease.

CASE 1.—The patient, a male, was first admitted on Oct. 8th, 1898. His family and personal history was negative as to pulmonary tuberculosis and alcohol, but a maternal uncle had died in an asylum. He said that he had some complaint which prevented him from working and thought it was due to someone "illwishing" him. He had attempted suicide. Physical examination revealed no evidence of disease save that the first sound of the heart was slightly rough in character and the pulse was 90. He was dejected and depressed but answered all questions readily and rationally, had a good memory, and realised his position. He was discharged recovered on June 6th, 1899. He was readmitted on Jan. 30th, 1902. His certificate again showed that he asserted himself to be suffering from an internal and incurable disease and had threatened to do away with himself. The pulse on this occasion was found to be 89 and of high tension; the heart was as before, but no trace of organic disease could be discovered. He exhibited good health and his melancholic symptoms seemed to be disappearing until the beginning of 1905 when he became very distressed, saying that he could not live. Examination of his chest in January showed the presence of consolidation in the apex of the left lung, and in February there were all the physical signs of a cavity. He began to lose weight, became anæmic and emaciated, had gastric irritability, and an uneven temperature. His pulse became feeble and he had copious night sweats and died on June 16th, 1905. He was never observed to cough during the whole course of his illness. His age at death was 52 years.

The necropsy revealed a large cavity in the left lung, which was full of pus and over two inches in diameter. Chronic pleuritic adhesions were present and the smaller bronchial tubes were choked with purulent material, most of the lung being in a state of consolidation. The weight of the organ was 60½ ounces. The heart was small, the muscle being soft, but the valves were competent. The spleen was soft and friable and the kidneys were apparently normal. The suprarenal gland of the right side was firmly attached to the kidney; that of the left was separate from its kidney and surrounded by a separate envelopment. Both suprarenals were enlarged, each weighing two and a quarter ounces, and in parts were fibrous and cartilaginous in feeling to the finger and gritty to the knife, other parts being studded with cysts which exuded a colloid material and cavities full of thick caseous pus, the left—i.e., on the same side as the affected lung—showing an abscess one inch in diameter. The liver was waxy. The brain was œdematous with distended ventricles. There was no anasarca, no pigmentation of the skin, no leucoderma, or deepening of the natural pigmentation in the usual sites. The hair showed no bronzing. There was a patchy, purple discolouration of the mucous membrane of the upper lip and of the gum of the upper jaw at its junction with the teeth, but no deposit of pigment on the tongue, the palate, or the lower lip.

There are several features of interest that rather tempt speculation as to the connexion between the mental state and the physical conditions. Was the lung affection previous to the suprarenal or *vice versâ?* Was the mental disorder secondary to the suprarenal? In the order of appearance by outward symptoms the melancholia was succeeded by the pulmonary tuberculosis and the latter had cut short the life of the patient and presumably the outward exhibition of the disease of the adrenal bodies. But these glands could hardly have been more diseased than they were and the patient's lungs were healthy till within a year of his death. His melancholia was a recurrence of a previous attack and was certainly previous to the pulmonary tuberculosis. Heredity is important in phthisical insanity and in cases of the latter an inherited tendency to insanity can usually be traced (Clouston). Is it that though the insanity appears before the pulmonary tuberculosis there is already a focus of the disease in the patient, though undiscoverable? Or can the depression of Addison's disease in a predisposed patient go on to insanity? One case with melancholia has been observed by Dr. Rutherford Macphail. While again drawing attention to the patient's main "delusion" I leave the discussion to abler judges.

CASE 2.—The patient, a male, aged 50 years, was admitted on March 31st, 1904. He was confused and semi-stuporose. He had been subject to epileptic fits for "some months." The pupils were contracted. The gait was shuffling and Romberg's sign was present. There was slight albuminuria. The breath sounds were normal. He remained dull and apathetic and suffered from nocturnal epileptic fits, crying out before them and falling or rolling over to the left. He was irritable occasionally. He was able to do outdoor work, his fits averaging 16 per month. In October, 1905, he had a succession of fits which left him feeble and stuporose. Bromide of sodium in 30-grain doses reduced the fits considerably but he died after several severe fits on Dec. 16th, 1905. He vomited once on the 15th.

Post mortem caseous nodules were found in both apices and in the bronchial glands. Miliary tubercles were found in the liver. No other organ with the exception of the brain was found to be affected to the naked eye. In the latter a curious condition presented itself. On running the hand over the cortex hard patches were felt where the pia mater was firmly attached. In the grey matter under, the cortex was firm and tough and fibrous in feeling. These scar-like nodules were less than pea-sized and in the cerebrum of each side but not in the frontal lobes, six such spots being on the right side and four on the left. In addition, in the cortex of the right occipital lobe a cyst with tough walls and containing caseous granules was found. The cyst was a quarter of an inch in diameter. None of these cortical nodules was encapsuled or easy to separate from the surrounding grey matter. In both lateral ventricles the ependyma was granular and small calcareous nodules of the size of a hemp-seed were found. In the left lobe of the cerebellum the white matter was firm and difficult to tear and the grey matter was almost non-existent. The white matter was contracted and gritty on section. Here one finds very suggestive signs. Slow-growing tumours are not rarely found in the brains of epileptic dements (Mott) and these during life may give rise to symptoms very like idiopathic epilepsy (Oppenheim, Mott). Small fibrous areas are occasionally found post mortem (Shennan) as if a tuberculous lesion had become quiescent. And tumours of the cerebellum (Mott) and of the parieto-occipital region (Risien Russell) may grow to a considerable size without evidencing focal symptoms. In cerebellar atrophy (Russell) epileptic convulsions are not rare and if a tuberculous seat in the cerebral convolutions contract and dry up it may cause epileptic attacks (Cotterill). That the last was the cause of the epilepsy and that affection of the cerebellum accounted for the fall to the left and the disturbance of gait is quite possible.

CASE 3.—A male, aged 25 years, was admitted on March 14th, 1905, suffering from acute delirious mania. There was a family history of pulmonary tuberculosis and the patient had been under treatment for the same disease in a sanatorium and been discharged cured. It was impossible to examine him properly but a cavity was found in the left lung. He remained violent and delirious till his death on March 17th. Post-mortem examination confirmed the diagnosis of a cavity, most of the remaining part of the lung being consolidated.

Here, on the basis that a toxæmia is the cause of this form of insanity, one must presume that mixed infection had occurred. Many are the causes assigned to this disease, quite as many, in fact, as to all diseases not known to be due to a specific organism, and pulmonary tuberculosis is in this array.[4] And whatever the cause may have been in this case, it is at least certain that the delirious mania occurred during the course of the disease.

In reviewing the records of these three cases I am aware the operation should be performed, if possible, in the pre-ascitic stage. Bunge also advises this early interference and quotes Turner, Rolleston, and the later writings of Talma to the same end. Rolleston also advises early operation. After discussing the manner in which the operation may benefit the patient, he says (p. 260), "When cirrhosis can be diagnosed with fair certainty in the pre-ascitic stage and when there are evidences of the disease such as hæmatemesis and splenic enlargement, operative interference has a much better chance than in the late stages," and again (p. 261), "The earlier the operation is undertaken the better the chance of improvement, or even arrest, of the disease."

[4] Blandford: Insanity

In consideration of the opinions of others and judging from the results in the present case it seems reasonable to hope that surgical interference will become more readily employed than heretofore and it is evident that the occurrence of hæmorrhages, and even severe hæmorrhages, is no barrier to operation but rather an indication for its use. The fact that the artificial anastomosis readily develops may be taken as a proof that portal obstruction is the main factor in the production of ascites as of hæmorrhages, notwithstanding the theory advanced by Harris, just quoted, that a chronic peritonitis is materially instrumental in its causation, and the toxæmic theory of Rolleston.

Referring briefly to the various methods of operating, it would seem that the greater the amount of anastomosis produced—*ceteris paribus*—the better should be the result. In the earlier operations means were taken to secure adhesion between the liver and diaphragm and fixation of the spleen, as well as suture of the mesentery to the abdominal wall. Bearing in mind that the patients are often seriously ill and that, particularly in cases of alcoholic origin, general anæsthetics are badly borne, it is evident that friction or curetting of the hepatic and diaphragmatic surfaces, insertion of a fold between them, and manipulation of the spleen cannot always be undertaken with reasonable safety. It is desirable, therefore, in the majority of cases, to select an operation which may be performed under a local anæsthetic. A simple suture of the omentum to the parietal peritoneum, such as was performed in this case, could readily be done with local anæsthesia, but the method described by Narath may not only be performed with Schleich's solution but seems to give a better result in a more speedy and more generous formation of compensatory circulation. The method consists in the formation of a subcutaneous pocket in the anterior abdominal wall and the insertion of a thick fold of omentum therein, care being taken that the suture of the abdominal wound is sufficient to prevent the occurrence of hernia but not enough to obstruct the circulation in the extruded omentum. Narath states that the skin around the wound becomes œdematous but that the tumefaction soon passes off and a ring of radially arranged venous radicles appears, sometimes as early as the second week. Describing the direction of the new venous flow, he mentions that of the superior epigastric to the femoral vein, the thoraco-epigastric to the lateral epigastric, and hence to the axillary vein, and one or more venous branches flowing upwards over the sternum and costal cartilages, with the remark that these mostly develop on the left side. No matter what operation is performed in the presence of ascites it cannot be expected that the fluid will cease to re-form until the collateral circulation has developed sufficiently to compensate. The insertion of a drainage-tube can hardly be recommended, though it formed part of the original operation, on account of the discomfort to the patient and the danger of septic infection, but relief may be given by one or more tappings should they be required. It may be mentioned also that the firm strapping of the abdomen is not now considered necessary. The operation performed in this case (*vide supra*) secured a broad area of contact between the omentum and the parietal peritoneum. It has the further advantages that it is easily and quickly performed; it may be done without general anæsthesia and there need be no impairment of the stability of the anterior abdominal wall.

In conclusion, it is submitted that in the simpler operations we have a means, comparatively free from risk, of alleviating the distressing symptoms of patients suffering from cirrhosis of the liver, and that such treatment should be undertaken in the early stages of the disease when possible, although it is not barred by the appearance of ascites or hæmorrhage. Admittedly useless in the last stages of the disease, when little glandular substance is left, when jaundice is present, and where renal or cardiac diseases complicate the condition, it is worthy of trial, even in well-marked cases, for the relief it sometimes affords.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF PURULENT PERICARDITIS SIMULATING EMPYEMA.

BY BASIL ADAMS, B.M., B.CH.OXON., M.R.C.S. ENG., L.R.C.P. LOND.,

RESIDENT MEDICAL OFFICER TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, E.

THE patient, a well-developed girl, aged four and a half years, was admitted into Victoria Park Hospital under the care of Sir Hugh Beevor, Bart., on June 15th, 1905. There was a history of an illness of one month's duration, commencing with what was diagnosed as influenza. This was followed by an attack of diarrhœa and vomiting, accompanied by abdominal pain. A fortnight before admission pneumonia was thought to have set in. During the whole month the child's feet had been slightly swollen, and at one time the left knee-joint (this latter had passed off before admission). She never vomited and for the few days before admission had not seemed feverish but her appetite had been capricious and she had only passed a small quantity of concentrated urine. Except for slight attacks of "bronchitis" her health had previously been good, she never having had any children's complaints. The family history was excellent.

On admission the patient seemed at first to be restless and fretful but when put to bed she lay quietly on her left side, slightly propped up. Considering her month's illness her condition seemed fair. Her colour was, however, pale and slightly bluish and her muscles were a little flabby. The temperature was 97·4° F.; the pulse was 140 per minute, of poor volume and tension, but easily counted; and the respirations were 40 per minute. On examination of the chest the left side was seen to bulge a little and not to move as well as the right on respiration. The heart's apex beat was not visible nor yet palpable. There was an absolutely dull percussion note from above the left clavicle all down the left side, extending two inches to the right of the middle line of the sternum. The heart sounds were heard over the lower part of, and to the right of, the sternum. The percussion note over the whole of the left back and axilla was equally dull. Breath sounds on auscultation were absent over the whole area except at the extreme left apex, where they were bronchial. There was well-marked puerile breathing over the whole of the right chest, with a few crepitations at the base. The hepatic dulness began low—at the seventh rib in the nipple line—and the liver could be felt one inch below the costal margin. The abdomen appeared otherwise to be natural. There was slight œdema of the feet and legs; the urine was scanty but it contained no albumin. A diagnosis of empyema was made and on the same evening an aspirating needle with two feet of rubber tubing attached to it was inserted one inch into the chest in the seventh intercostal space in the left posterior axillary line. In this way 22 ounces of pus were withdrawn which was inoffensive and yellowish in colour. The aspiration was accompanied by no coughing, the child dozing while the fluid ran away. On the next day the patient, though very ill, seemed to be no worse, but, on examining the back of the chest, signs of a localised pneumothorax were found to be present around the place of insertion of the aspirating needle. On the two ensuing days the child's condition became worse; she was taking her food very badly and was becoming more restless at night; the signs of

In the literature of the subject various claims are set forth in the matter of priority of the idea of producing an anastomosis between the portal and the systemic circulations, and it would serve no good purpose to discuss here the rival claims of those who have employed allied artifices to attain that end, but the names of Talma of Utrecht and Morison are so closely associated with the early publication of such procedures that they are likely to be accepted as distinctive. Although the surgical treatment of the circulatory difficulties in cirrhosis is of comparatively recent date there have already appeared many reports of operations and of different varieties of procedure, as well as conflicting estimates of the value of surgical interference. It is no matter for surprise that operations have been undertaken in cases that were unsuitable, both with reference to the ability of the patient to undergo any operation and with reference to the possibility of improvement in view of the condition of the liver itself or of other vital organs such as the heart and kidneys. For that reason the statistics, taken over all, are of little value unless there be given with each case sufficient information to enable a classification to be made.

It is necessary to know as definitely as possible the objects to be gained in order that the success of the result may be estimated. Osler sums up the prospects of the treatment very concisely when he states that "ordinary cirrhosis of the liver is an incurable disease. ...... So far as we have any knowledge, no remedies at our disposal can alter or remove the cicatricial connective tissue which constitutes the *materia peccans* in ordinary cirrhosis. On the other hand, we know that extreme grades of contraction of the liver persist for years without symptoms when the compensatory circulation exists." Frazier gives the maximum scope of the operation when he states that: "This operation purports to open another channel for the relief of the portal circulation. I say another channel because there already exists a more or less free collateral circulation between the systems of the portal vein and the inferior vena cava." He then indicates the natural channels of anastomosis, which are perhaps better given by Osler: "1. The accessory portal system of Sappey, of which important branches pass in the round ligament and suspensory ligaments and unite with the epigastric and mammary systems. These vessels are numerous and small. Occasionally a large single vein, which may attain the size of the little finger, passes from the hilus of the liver, follows the round ligament, and joins the epigastric veins at the navel. Although this has the position of the umbilical vein it is usually, as Sappey showed, a para-umbilical vein—that is, an enlarged vein by the side of the obliterated umbilical vessel. There may be produced about the navel a large bunch of varices, the so-called caput Medusæ. Other branches of this system occur in the gastro-epiplöic omentum, about the gall-bladder, and, most important of all, in the suspensory ligament. These latter form large branches, which anastomose freely with the diaphragmatic veins, and so unite with the vena azygos. 2. By the anastomosis between the œsophageal and the gastric veins. The veins at the lower end of the œsophagus may be enormously enlarged, producing varices which project on the mucous membrane. 3. The communications between the hæmorrhoidal and the inferior mesenteric veins. The freedom of communication in this direction is very variable and in some instances the hæmorrhoidal veins are not much enlarged. 4. The veins of Retzius which unite the radicles of the portal branches in the intestines and mesentery with the inferior vena cava and its branches. To this system belong the whole group of retro-peritoneal veins which are in most instances enormously enlarged, particularly about the kidneys, and which serve to carry off a considerable portion of the portal blood."

In the earlier operations advantage was taken of the proximity of the liver to the diaphragm, and the adjacent surfaces were rubbed so as to promote adhesion, and for a like purpose the spleen was similarly treated. More recently some surgeons have endeavoured to get the greatest amount of anastomosis by fixing a large portion of omentum in an extra-peritoneal pocket made in the anterior abdominal wall. The methods will be referred to later but these are mentioned now to indicate some of the varieties of procedure by which artificial anastomosis between the portal and systemic circulations may be obtained. It would be comparatively easy to suggest further methods of producing adhesions calculated to increase this anastomosis and it is not an unlikely suggestion that the cases of ascites in this disease, successfully treated by simple and prolonged drainage, owe their recovery to multiple adhesions and therefore multiple anastomoses.

If the whole question of surgical interference depended on the non-sufficiency of the natural collateral circulation the answer would be comparatively easy, for the occurrence of ascites, hæmatemesis, and epistaxis, with varices at the anus and umbilicus, and distended venules at the lower costal margins, &c., would indicate the need for assistance. It will be evident, however, that when the disease is so far advanced that the liver substance is mostly destroyed by the cicatrising connective tissue, operative measures for the relief of the portal circulation are too late; indeed, the occurrence of jaundice in this disease is generally held to bar surgical intervention. So, too, the presence of marked kidney or cardiac lesions is a decided objection. Some observers hold that the occurrence of hæmorrhage is a sign that the fibrotic changes in the liver are so far advanced as to negative surgical intervention. Bunge mentions as further contra-indications the presence of urobilin in the urine and pigmentation of the skin. That may be taken as a general statement of the limits of operative interference. Rolleston in referring to the bad effects which may result from excessive development of this venous anastomosis remarks that: "In the first place, if communications are extensive it necessarily follows that a considerable quantity of blood carrying the products of digestion will pass directly into the general circulation instead of passing through the liver. If the anastomosis is very free the condition would resemble that in Eck's fistula or the experimental communication between the inferior vena cava and the portal vein, which results in all the portal blood passing into the inferior vena cava." He refers to experiments carried out on these lines by Hahn, Nasse, Nencki, and Pawlow, in which effects equivalent to those of hepatic insufficiency resulted, and he quotes Stockton in support of a statement that excessive development of the collateral circulation may lead to a toxæmic condition verging on uræmia. Remarking that one of Morison's patients, "after an operation for the surgical relief of ascites, was alternately excited and depressed for three weeks," he suggests that possibly a very free anastomosis between the portal and general venous systems, while relieving portal engorgement may lead to arterio-sclerosis and granular kidneys." In the second place, hæmorrhage may take place from rupture of the dilated venous anastomosis, and he quotes some cases where a hæmatoma occurred in the anterior abdominal wall, near the middle line, in patients suffering from hepatic cirrhosis.

The advantages claimed for the operation are the relief of those symptoms which are directly due to the retardation of the portal circulation. In that category ascites and hæmatemesis may be regarded as the most prominent, while sickness, epistaxis, and hæmorrhoids occupy a position of secondary importance. These constitute the burden which the patient has to bear, and though no claim is made that the relief of the portal circulation will check the course of the disease, it is apparent from the number of cases on record that much relief is obtained, while in a number of instances complete cessation of the symptoms results. In an analysis of 14 cases collected by Frazier, and excluding those in which there was some error of technique or of diagnosis or in which the operation was contra-indicated, one patient was living but unimproved, one was slightly improved, and six were living and free from ascites at periods of 3, 4, 6, 24, 24, and 26 months respectively. Frazier believes that in properly selected cases, where the liver is cirrhotic, where there is reason to believe that the liver cells are not devoid of function, where internal medication and paracentesis fail to afford relief, and where there is no reasonable contra-indication, the operation has a future.

Rolleston (pp. 259–60), believing that the ascites is due to toxæmia, suggests that the beneficial effects of operative interference are due (1) to the reduction of the amount of blood passing through the liver diminishing the toxæmic condition of the blood by enabling that organ to deal more satisfactorily with the quantity of blood which does pass through; and (2) to the relief of vascular venous engorgement which permits of a better arterial supply, improves the nutrition of the liver cells, and so favours a compensatory hyperplasia. Harris goes further and believing that the ascites is not solely due to portal obstruction but also to chronic peritonitis resulting from the cirrhosis, suggests that

SUSSEX COUNTY HOSPITAL.

A CASE OF CARCINOMA OF THE STOMACH; PYLORECTOMY.

(Under the care of Dr. E. HOBHOUSE and Mr. R. F. JOWERS.)

THE patient, a married woman, aged 57 years, was admitted in September, 1905, under the care of Dr. E. Hobhouse and transferred to Mr. R. F. Jowers for operation. Her first attack of gastric pain occurred when she was 27 years of age, chiefly after food. For the last five years she had constantly had pain at the epigastrium after food. Two years previously she also had pain in the left hypochondrium and about the same time noticed a small lump to the left of the middle line, which had gradually increased in size. There had been no hæmatemesis but frequent vomiting with relief of pain, no constipation, or melæna. In the abdomen, just to the left of the middle line, was a hard mass which was moveable and of about the size of a Tangerine orange. The liver was not enlarged and there were no enlarged cervical glands. When seen by Mr. Jowers at the end of September she was vomiting after everything she took and was having opiates daily for the relief of pain.

Operation was performed on Oct. 2nd. Mr. Jowers opened the abdomen and found the tumour to be freely moveable and situated at the pyloric end of the stomach. It involved about one-third of the stomach and there were glands in the omenta above and below the growth. The omenta having been ligatured well away from the glands, clamps were applied to the duodenum and the stomach and the included portion was removed with scissors. The opening in the stomach was closed with two rows of continuous sutures. As the cut end of the duodenum could easily be approximated to the stomach without tension it was attached to a vertical incision made in the posterior wall of the stomach about an inch behind the line of section by two rows of continuous sutures. The great omentum was then turned up and attached by one or two points of sutures over the junction and the abdomen was closed. Examination of the specimen showed it to involve both anterior and posterior walls, and Dr. F. G. Bushnell, after microscopical examination, reported it to be scirrhous carcinoma.

The patient made an uninterrupted recovery. When seen recently she was in good health, had gained flesh, and was able to eat ordinary food without pain.

Remarks by Mr. JOWERS.—From the history of the early attacks of pain it seems probable that this is a case of malignant disease following upon gastric ulcer. The importance of early diagnosis cannot be too strongly insisted upon and it was fortunate that after the known existence of a lump for two years excision was still practicable. Quite recently I have operated upon two cases in which, owing to involvement of adjacent parts, removal was impossible and a palliative gastro-enterostomy only was practicable.

EAST SUFFOLK AND IPSWICH HOSPITAL.

A CASE OF APPENDICITIS COMPLICATED BY PERFORATED DUODENAL ULCER.

(Under the care of Dr. JOHN GUTCH.)

FOR the notes of the case we are indebted to Mr. E. G. D. Milsom, house surgeon.

The patient was a man, aged 36 years, who was treated at the East Suffolk and Ipswich Hospital under the care of Dr. Gutch. The following account of his illness previously to admission was given by the patient. He awoke on the morning of March 1st with intense abdominal pain, which by March 2nd had settled in the right iliac fossa; on this date he had also vomited twice and his bowels had been well opened. He had never before suffered from attacks of a similar nature, the only point of interest in his previous history being that he was a heavy drinker and had suffered from indigestion with occasional attacks of hæmatemesis.

When seen in the ward on March 3rd the patient was lying comfortably on his back and not looking very ill. His tongue was furred, his temperature was 101° F., and his pulse was 100. The abdomen moved badly on respiration but showed no obvious fulness. Rigidity was present on the right side but was most marked over the right iliac fossa, where there were also impaired resonance and tenderness on pressure. Rectal examination yielded no information. A blood count showed a leucocytosis of 20,000. Great difficulty was experienced in examining the patient as he was extremely fat. A diagnosis of acute appendicitis was made and, in view of an increasing pulse-rate and the presence of a leucocytosis, immediate operation was decided on.

An incision was made through McBurney's point and on opening the abdominal cavity, after some difficulty, the cæcum was found bound to the neighbouring coils by adhesions. In breaking these down a small quantity of dark offensive pus was evacuated from a cavity behind the appendix through the apex of which a fæcal concretion had perforated. Removal of the appendix was impracticable as small portions broke away on the slightest manipulation; a large drainage tube was therefore inserted and the lower half of the abdominal wound was closed.

For 24 hours the patient seemed to be doing well; he passed a good night and felt comfortable; his temperature was 99·2°. His pulse was good and the abdominal wound was draining well. He had been fed on nutrient enemata only. At 1 A.M. on the night of March 4th he vomited a few ounces of dark tarry blood; he did not complain of pain and had a good tension pulse with a temperature of 99°; his abdomen moved well. Morphine was administered hypodermically and adrenalin and ice by the mouth; but the hæmatemesis continued incessantly and the patient by 4 A.M. was suffering from all the symptoms of severe hæmorrhage. In spite of all remedies he continued to vomit and died on March 5th, 13 hours after the onset of hæmatemesis and 41 hours after operation. Taking into consideration the previous history of alcoholism and hæmatemesis, the most probable diagnosis seemed to be rupture of an œsophageal pile complicating cirrhosis of the liver.

Necropsy.—The post-mortem examination was performed four hours after death. The appendix region was completely shut off from the general peritoneal cavity. It was impossible to ascertain the amount or nature of the fluid in the abdominal cavity, as fæces escaped from the intestines which were wounded when opening the abdomen, but the peritoneum presented no evidences of inflammation. In the first part of the duodenum close to the pylorus there was a perforation half an inch in diameter. There were only a few adhesions in the neighbourhood. The ulcer was single with no induration round it and had a "punched-out" appearance. No open vessel was found to account for the hæmatemesis. The liver showed well-marked fatty cirrhosis and the other organs were normal.

Remarks by Dr. GUTCH.—The association of hæmatemesis with appendicitis, though one of the rarer complications, is not unknown. Kelly in describing the symptoms of acute appendicitis says, "Hæmatemesis has been described by Treves, by Dieulafoy, and by Matheson and others, and is attributed generally to toxic degeneration of the gastric mucous membrane with erosion of small blood-vessels," and the hæmatemesis in the above case might presumably have been of that nature, though with the previous history cirrhosis seemed a much more probable diagnosis. I can find no mention of the degeneration and erosion going on to ulceration, and the association of the perforating duodenal ulcer was in this case, I have no doubt, an unfortunate coincidence and in no way a sequel of the appendicitis. The previous hæmatemesis was also probably due to duodenal ulceration.

DEATHS OF CENTENARIANS.—The *Times* of April 25th states that Captain Edward Dumaresq, late of the Honourable East India Company's service, died on April 16th, aged 104 years, at the residence of his son, Mount Ireh, Longford, Tasmania.—The death occurred at Pontrhydyfen, Glamorgan, on April 24th, of Mrs. Mary Thomas, aged 105 years. Up to a few weeks ago she was quite active and possessed a clear memory. Her grandmother lived beyond 100 years.

pneumothorax now extended from the spine of the left scapula nearly to the base where there was still dulness to percussion. On June 20th, as there was no improvement, it was decided to resect a portion of the eighth rib on the left side. This was done in the posterior axillary line, but as soon as a small opening was made in the pleura the child collapsed and died. No pus came from the pleural cavity but a few drachms of turbid fluid and air escaped.

A post-mortem examination was made on the next day; a small quantity of turbid fluid was found in each pleural cavity but the pericardium contained 15 ounces of pus similar to that drawn off by aspiration, in addition to much curdy material. On further opening up the pericardial cavity the hand could be introduced into it and it could be felt to extend as high as the left clavicle, to the ribs in the left axilla, and also three inches to the right of the middle line of the sternum. The wall of the pericardium was about one-sixth of an inch in thickness. The left lung was completely collapsed; near its base could be seen punctures where the aspirating needle had entered and left it. The endocardium was normal. The liver weighed 20 ounces and showed signs of congestion, as did also the kidneys. Cultures were taken of the pus removed by aspiration and of the pus found in the pericardium post mortem; in both cases a pure culture of staphylococcus pyogenes albus was obtained.

Note by Sir HUGH BEEVOR.—Dr. Adams reports here an instance of inefficient diagnosis which has been the usual experience in published cases of this great distension of the pericardium. The mere calling attention to this somewhat rare condition may prevent its being overlooked when consulting as to operation of resection of rib after the discovery of pus by exploratory puncture.

Victoria Park, E.

A CASE OF COMPOUND FRACTURE OF THE PELVIS.

BY EDWARD P. LEAVY, L.R.C.P., L.R.C.S. IREL.,

GOVERNMENT MEDICAL OFFICER, GERALDTON, JOHNSTONE RIVER, QUEENSLAND.

THE patient in the present case was a woman, aged 50 years, and weighing 12 stones, who was brought into the local hospital after a buggy accident. She was in a collapsed state and the front of her dress was soaked with blood which came from a rupture of the upper lip extending as far as the nasal fold and exposing the upper jaw on the left side. There were no other injuries on the face or head. She had no teeth. On removing her clothes her under-garments had much blood upon them which she said had come from "the front passage." She complained of great pain on the left side, with inability to move the corresponding leg. As she lay on her right side after the removal of her clothes the left hip and buttock were observed to be flattened and seemed to have sunk away into the right side. The vaginal hæmorrhage had ceased. Under chloroform the hip-joint was freely moved, the head of the bone was in position, and the leg was uninjured, but on passing the finger into the vagina a large roughened surface of bone could be felt protruding through the left side of that cavity, evidently a fracture of the inferior ramus of the ischium immediately in front of the tuberosity. Reduction was accomplished with the patient on her back by hooking the left leg over the surgeon's arm, and on raising the limb the roughened surface of bone was felt to sink back from its unnatural position. The leg was then bandaged on a McIntyre's back splint screwed up to an acute angle and it was also deemed advisable to place the right leg in a similar splint. The lip was sutured. On a catheter being passed the urine came away clear and was normal in reaction; the bowel was emptied by enemata and a normal motion was passed. The patient could empty the bladder and the bowel naturally in a few days, but on one occasion—namely, on the eighth day after the accident—she commenced to complain of sharp pains whilst passing urine and some blood-stained sediment came away. The bladder was then washed out for a few days and a diuretic mixture was given when all pain and disability ceased. The seat of the fracture was occasionally examined but no displacement of the bone could be felt; the pubic arch was regular; nothing satisfactory could be demonstrated as to the injury to the left sacro-iliac articulation except the patient's subjective symptoms. By the end of the fifth week a trial of the patient's progress was made by assisting her to sit upright and an opportunity was then offered of thoroughly examining the sacral region. Both buttocks were uniform in appearance and no pain was elicited on movement. She was further assisted to stand and when with help she managed to take a few steps round the ward she complained only of feeling giddy and weak.

Fracture of the pelvis is, so far as I know, sufficiently rare to deserve recording, especially on account of the limited range of injury (if any) to the pelvic viscera. I look upon the rupture of the upper lip as the result of *contre-coup*. The patient was wearing a full set of false teeth when she sustained her injuries but they have, strange to say, been lost since the accident.

Geraldton, North Queensland.

NOTES ON ANOTHER CASE OF POISONING BY NITRO-BENZOL.

BY CHARLES H. GREGORY, M.A., M.B. CANTAB.

IN THE LANCET of Jan. 13th, p. 88, Staff Surgeon A. H. H. Vizard recorded a case of poisoning by nitro-benzol. A few notes on another case may be of interest. A short time ago a youth, aged 17 years, swallowed at least one mouthful of this substance out of a bottle which he mistook for one he had half emptied of lemonade and intended to finish. This occurred about noon and his stomach was empty. It was about 20 minutes afterwards that I saw him and during the next half-hour administered copper sulphate to the amount of ten grains, he only then vomiting when I was inserting a syphon tube to wash out his stomach, thinking it inadvisable to wait longer. The patient left my surgery feeling no ill effects but was noticed about an hour or two later to be becoming bluish about the lips. About 5 P.M. I saw him at home; he was in bed complaining of constant vomiting, the ever-present taste of the poison, headache, faintness, and giddiness on attempting to rise. His breath and what little mucous was ejected from the stomach still gave the characteristic odour of "artificial oil of almonds." The pulse was weak and easily compressible and examination of the heart showed the presence of a systolic murmur. The whole body was bluish in colour, the face, especially the lips and tongue, being almost black. Full instructions were given that the boy was not to be left during the night and that in the event of any change I was to be sent for immediately. Meanwhile a dose of calomel was given and a mixture of bismuth and compound tincture of morphine and chloroform to combat the sickness. Brandy was also given, with directions to increase the amount if necessary. The next morning saw the patient a little better, but the headache continued for three days, no coma supervening. The colour of the skin did not become natural for five or six days and by that time the cardiac murmur had entirely disappeared. A tonic containing iron and arsenic rapidly improved the patient's condition and he returned to work in between two and three weeks as well as ever. The urine was dark throughout and looked as if it contained blood-pigment, but beyond the fact that it was shown to give the reaction for picric acid and did not contain albumin circumstances did not permit of an exhaustive examination of it.

Apiti, New Zealand.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—The pass list of the April examinations has recently been issued. Of seven candidates who entered for the Intermediate Examination the following six passed: C. T. Bennett, B.Sc. Lond., S. H. Groenewoud, B. R. James, G. R. W. Lawson, E. H. Merritt, B.Sc. Lond., and C. A. Wonham, B Sc. Lond. In the Final Examination for the Associateship (A.I.C.) the following three out of four candidates examined in the branch of Mineral Chemistry passed: G. N. Bacon, Assoc.R.C.Sc. Lond., B.Sc. Lond., F. M. G. Johnson, M.Sc. Montreal; and E. J. Wilson, B.A. Cantab. Of four in the branch of Metallurgical Chemistry one passed: H. J. Bailey. Two candidates presented themselves in Organic Chemistry and both passed: L. H. Berry and O. W. Stickland, B Sc. Lond. Of seven who entered in the branch of the Analysis of Foods and Drugs and of Water, including an examination in Therapeutics, Pharmacology, and Microscopy, the following five passed: B. J. Eaton, W. R. Mummery, F. L. Okell, R. P. Page, and R. G. Pelly.

PATHOLOGICAL SOCIETY OF LONDON.

Conveyance of Plague by Feeding.—Bacillus Equi.—Carcino-sarcoma of Larynx.—Classification of Pathogenic Streptococci.

A LABORATORY meeting of this society was held at St. Bartholomew's Hospital on May 1st, Dr. F. W. ANDREWES being in the chair.

Dr. E. KLEIN showed lantern slides illustrating the successful Inoculation of Rats, Guinea-pigs, and Mice with Plague by means of Feeding Experiments. The material used was dried gelatin and agar cultures of the organism.

Dr. KLEIN also showed a lantern slide illustrating Bacillus Equi in the blood of a rabbit dead after intravenous inoculation by this organism.

Mr. FRANK A. ROSE showed a microscopic section of a Tumour removed from the Larynx. The tumour had been removed by the operation of thyrotomy from the interior of the larynx. Microscopic examination revealed an unusual appearance. Two-thirds of the tumour had the appearance of a spindle-celled sarcoma, whilst the remaining portion had the appearance of a squamous-celled carcinoma. An enlarged lymph gland showed no evidence of malignant disease.
